Long Papers
Charting the Australian COVID-19 Information Flow: Implications for Information Policy ................................................................. 1
Afzal, Waseem; Du, Jia Tina; Haider, Ammar; An, Lu; Khoir, Sairiotu; Batool, Syeda Hina
Al Haque, Ebtesam; Smith, Angela D. R.; Johnson, Brittany
Electronic Health Records and Cyber Hygiene: A Qualitative Study of the Awareness, Knowledge, and Experience of Physicians in Kuwait ................................................................................................................................ 21
Alkhaledi, Reem; Hawamdeh, Suliman
“Finding a Way To Say ‘No’”: Library Employees’ Responses to Sexual Harassment as Emotional Labour ........................................................................................................................................................... 31
Allard, Danielle; Oliphant, Tami; Lieu, Angela
Stronger Than Yesterday: Investigating Peoples’ Experiences of View Strengthening on Social Media .................................................................................................................................................................................... 41
Beall, Sabrina; Makri, Stephann; McKay, Dana
The Hipátia Model: Paths toward the Brazilian Archival Digital Preservation Era .................................................................................... 53
Braga, Tiago; Alves, Larissa
‘Routine Infrastructuring’: How Social Scientists Appropriate Resources to Deposit Qualitative Data to ICPSR and Implications for FAIR and CARE .................................................................................................................................................................................. 61
Bratt, Sarah
Exploring Information Behavior Patterns in Response to False and Misleading Health Information ......................................................................................................................................................................................... 73
Bressel, Paulina; Dewitz, Leyla; Greifeneder, Elke
Understanding Reactions in Human-Robot Encounters with Autonomous Quadruped Robots ....................................................................................................................................................................................... 86
Chan, Yao-Cheng; Hauser, Elliott
Engaging Participants in Online Interviews: Lessons Learned from Implementing a Participatory Visual Approach in Two Explorative Health Information Behavior Studies ................................................................................................................................ 98
Dewitz, Leyla
Mixed Methods Framework for Understanding Visual Frames in Social Movements ......................................................................... 111
Dozal, Laura W.
Enriching Library Holdings for English Language Learners: Applying Traditional Readability Formulas and Modern Cohesion Methods to Film ............................................................................................................................................................................... 121
Durward, Matthew; Organisciak, Peter
Mutual Sustainability among Communities and Their Knowledge Infrastructures ................................................................................................. 133
Fenlon, Katrina; Reza, Alia; Grimmer, Jessica; Wagner, Travis
Audit Team Communication and Risk in Trustworthy Digital Repository Certification ................................................................................................................................. 145
Frank, Rebecca D.; Wylie, Jessica
Development of a Recordkeeping Culture in Community-Based Organisations in Bangladesh ................................................................................................................................................................................ 156
Frings-Hessami, Viviane; Hossain, Md. Khalid; Bhowmik, Joy; Meem, Jemima Jahan
Voices of the Stacks: A Multifaceted Inquiry into Academic Librarians’ Tweets ........................................................................................ 166
Ghosh, Souvik; Thajudeen, James
A Guided Tour Study of the Untidy but Inspirational PIM of Visual Artists .............................................................................................. 179
Hellmich, Helene; Dinneen, Jesse David
The Mining of China's Policies against COVID-19 from Policy Targets and Policy Tools Perspectives .................................................................................................................................................................................. 192
Huo, Chaoguang; Li, Xinru; Zhang, Chenwei; Huo, Fanfan
Multi-Modal Crisis Discourse and Collective Sensemaking on TikTok ..................................................................................................... 203
Hou, Christy; Owen-Smith, Alexander; Joh, Una; Duan, Yiran; Hemsley, Jeff
Examining Social Media Policy and Records Management in Massachusetts Municipal Governments ..................................................213
Kriesberg, Adam

Sharing Qualitative Interview Data in Dialogue with Research Participants ..................................................................................223
Kvale, Live Händlykken; Pharo, Nils; Darch, Peter

Welding Instructors’ Perspectives on Using AI Technology in Welding Training ..............................................................................233
Lassiter, Tina; Collier, Chelsea; Fleischmann, Kenneth R.; Greenberg, Sherri R.

In a Perfect World: Examining the Desires and Realities for Digitized Historical Image Archives ..........................................................244
Late, Elina; Ruotsalainen, Hille; Kumpulainen, Sanna

Person-Oriented Ontologies Analysis for Digital Humanities Collections from a Metadata Crosswalk Perspective ..........................................................................................255
Liu, Rui; McKay, Dana; Buchanan, George

Negativity Bias During Information Seeking, Processing, and Sensemaking about a Policy Debate: An Eye-tracking Experiment ..................................................................................................................267
Liu, Yingtong; Zhang, Jiajia; Zhang, Pengyi

What Is a Person? Emerging Interpretations of AI Authorship and Attribution ..........................................................................................279
Moulaison-Sandy, Heather

“How Do You Measure a Relationship?” Assessment and Evaluation Challenges of Knowledge Exchange Activities in Information Work ..........................................................................................291
O’Brien, Heather; McDavid, Kristina; Yao, Jess

An Investigation of the Use of Theories in Misinformation Studies ........................................................................................................293
Ogbadu-Oladapo, Lydia; Chung, Hsin-Husan; Li, Jiayuan; Chen, Jianguing

Meeting People Where They Are: Hyper-local Engagements Around COVID-19 Misinformation in New Jersey ..........................................................................................303
Paris, Britt; Costley White, Khadijah

From Principles to Practice: Comparative Analysis of European and United States Ethical AI Frameworks for Assessment and Methodological Application ............................................................................327
Pierson, Cameron M.; Hildt, Elisabeth

Data Flourishing: Developing Human-Centered Data Science through Communities of Ethical Practice ..........................................................................................338
Poole, Alex H.

“Get Our Feet Wet and Hands Dirty”: Black Community-Based Librarianship and the Fight Against Information Poverty, 1940-1975 ..........................................................................................353
Poole, Alex H.

Study on the Characteristics of Cross-Domain Knowledge Diffusion from Science to Policy: Evidence from Overton Data ........................................................................................................368
Ren, Chao; Yang, Menghui

The New Information Retrieval Problem: Data Availability ........................................................................................................379
Sharma, Sarika; Wilson, James; Tian, Yubing; Finn, Megan; Acker, Amelia

A Study of COVID-19 Information Behaviors among Black Americans ..........................................................................................388
Stewart, Brenton J.; Ju, Boryung; Walker, Jessie J.

“Garbage Bags Full of Files”: Exploring Sociotechnical Perceptions of Formats within the Recovery and Reuse of Scientific Data ........................................................................................................396
Wagner, Travis L.; Fenlon, Katrina; Sorensen, Amanda

Characterizing and Early Predicting User Performance for Adaptive Search Path Recommendation ........................................................................................................408
Wang, Ben; Liu, Jiqun

Finding the Aha! Moment of Search: A Preliminary Examination of Insight Learning During Search ........................................................................................................421
Wang, Xinyue; Liu, Changle

“Our Metadata, Ourselves”: The Trans Metadata Collective ........................................................................................................433
Watson, B. M.; Murphy, Devon; Schaefer, Beck; Huang, Jackson

Curating for Contrarian Communities: Data Practices of Anthropogenic Climate Change Skeptics ........................................................................................................442
Wofford, Morgan F.; Thomer, Andrea K.

Hyper-Local Fear of Crime: Identifying Linguistic Cues of Fear in Crime Talk on Reddit ........................................................................................................456
Wu, Qunfang; Hemsley, Jeff

**Computational Thematic Analysis of Poetry via Bimodal Large Language Models**

Chen, Miaomiao; An, Lu; Li, Gang

**From Ice Cores to Dinosaurs: Curation Behaviors of Physical Collections Managers**

Ayeni, Philips

**How Information Science Research Can Contribute to the Development of Dementia-Friendly Potential of Open-Ended Questions**

Eriksson-Backa, Kristina; Enwald, Heidi; Hivonen, Noora; Huvila, Isto

**Involving Older Users in Design of Patient Accessible Electronic Health Records: Exploring the Potential of Open-Ended Questions**

Dodson, Samuel; Sinnamon, Luanne; Kopak, Rick

**Seize the Initiative: In-Process LGBTQ+ Research Findings and Their Impact on Connecting Practices in New Zealand GLAMU Institutions**

Choi, Wonchan; Zhang, Yan; Stvilia, Besiki

**Studying Lived Experience and Automated Systems: The Case of Universal Credit**

Currie, Morgan; Podoletz, Lena

**Digital Ownership: The Case of E-Books**

Zhao, Liang; Zeng, Zihan; Liu, Jiayi; Zhang, Yachen

**Refueling Mental Health: Digital Reading Predicts Psychological Resilience for Left-behind Children in Rural China**

Zhao, Liang; Zeng, Zihan; Liu, Jiayi; Zhang, Yachen

**Navigating Academic Transitions**

Alon, Liliach

**"I Am in a Privileged Situation": Examining the Factors Promoting Inequity in Open Access Publishing**

Ayeni, Philips

**An Empirical Study Using Convergent Cross Mapping**

Chen, Miaomiao; An, Lu; Li, Gang

**Computational Thematic Analysis of Poetry via Bimodal Large Language Models**

Choi, Kahyun

**Exploring Applications and User Experience with Generative AI Tools: A Content Analysis of Reddit Posts on ChatGPT**

Choi, Wonchan; Zhang, Yan; Stvilia, Besiki

**Studying Lived Experience and Automated Systems: The Case of Universal Credit**

Currie, Morgan; Podoletz, Lena

**Conversations on the Invisibility of PIM, Approaching Themes, and New Avenues of Research**

Cushing, Amber L.; Reyes, Vanessa; Ferguson, Robert D.

**Navigating Academic Transitions**

Alon, Liliach

**Seize the Initiative: In-Process LGBTQ+ Research Findings and Their Impact on Connecting Practices in New Zealand GLAMU Institutions**

Choi, Wonchan; Zhang, Yan; Stvilia, Besiki

**Involving Older Users in Design of Patient Accessible Electronic Health Records: Exploring the Potential of Open-Ended Questions**

Dodson, Samuel; Sinnamon, Luanne; Kopak, Rick

**How Information Science Research Can Contribute to the Development of Dementia-Friendly Potential of Open-Ended Questions**

Eriksson-Backa, Kristina; Enwald, Heidi; Hivonen, Noora; Huvila, Isto

**An Examination of the Real-World Appraisal Practices of Archivists**

Faulkner III, James D.; Kim, Jeonghyun

**Trust in Search Engines: Developing a Trust Measure and Applying It in an Experiment**

Häußler, Helena

**Information in Crisis Mode? A Conceptual Analysis of the Information Crisis Discourse**

Hicks, Alison; Noone, Rebecca

**Information Barriers Caused by Marginalization and Norms: Experiences of Transgender and Non-Binary People**

Huttunen, Aira

**Practices of the “Library as Place” in Norway**

Kawamoto, Marika; Koizumi, Masanori

**Using Explainable AI to Understand Team Formation and Team Impact**

Xu, Huimin; Saar-Tsechansky, Maytal; Song, Min; Ding, Ying

**Social VR: A Promising Platform for Enhancing Mental Wellness among College Students**

You, Xinyue (Sally)
Development and Validation of a Data Literacy Assessment Scale
Kim, Jeonghyun; Hong, Lingzi; Evans, Sarah; Oyler-Rice, Erin; Ali, Irhamni

Trend of Collaboration in STEM Education in Informal Learning Institutions Based on IMLS-funded Projects
Kim, Soo Hyeon; Yoon, Ayoung; Seo, Jooyoung

Exploring the Relationship between Sci-Hub and Medical Literature
Kjellström, Zakayo

Teenagers and Videoconference Fatigue: A Preliminary Analysis from an Affordance-based Approach
Lee, Chei Sian; Li, Benjamin Junting; Wu, Qian

A Preliminary Investigation of the Effects of Open Review on Citation Impact
Liang, Tiantian; Zhong, Zhuosheng; Zuo, Zhiya; Li, Hui; Wang, Xi

Transforming Indigenous Knowledges Stewardship Praxis through an Ethics of Care
Liew, Chern Li; Lipscombe, Ailsa

Investigating Academic Graph-Based Factors behind Funding Success in National Institutes of Health
Lin, Tianqianjin; Wang, Qian; Jiang, Zhuoren; Yuan, Weikang; Huang, Cui; Mabry, Patricia; Liu, Xiaozhong

Developing Management and Leadership Course: A Case Study
Lopatovska, Irene; Parasnis, Eesha

Geofence Warrants, Geospatial Innovation, and Implications for Data Privacy
McGowan, Catherine

Theorizing Cultural Heritage Informatics as the Intersection of Heritage, Memory, and Information
Modrow, Sebastian; Youngman, Tyler

When Push Comes To Pull: Place, Mobility, and Information Access for Vehicle Residents
Montague, Kaitlin E.

Anti-Black Racism, Anti-Immigrant Sentiment, and Misinformation: A Recipe for Profound Societal Harm
Ndumu, Ana; Orie Chuku, Nenna

Tuning Out the Noise: Benchmarking Entity Extraction for Digitized Native American Literature
Parulian, Nikolaus Nova; Dubnicek, Ryan; Evans, Daniel J.; Hu, Yuerong; Layne-Worthy, Glen; Downie, J. Stephen; Heaton, Raina; Lu, Kun; Orr, Raymond I.; Magni, Isabella; Walsh, John A.

Older Adults’ Attitudes toward Digital Technology and Perceptions of Its Usefulness: Example of the City of Osijek, Croatia
Petr Balog, Kornelija; Faletar, Sanjica; Jakopčić, Tomislav

Polkinghorne, Sarah

Below the Surface: Analyzing the Level of Detail and Depth of Coverage in Library and Information Science Syllabi Addressing Disability and Accessibility
Simons, Rea N.; Mallary, Kevin J.; Nikiema, Jackie; Dorman, Evan J.; Copeland, Clayton A.

Detection of Musical Borrowing Using Data Science
Walczak, Steven; Moore-Pizon Jr., Thomas E.

Connecting iSchools and Society Through Scientific Research: A Worldwide Exploratory Study
Wang, Di; Zhou, Lihong; Chowdhury, Gobinda

Using Ontology to Organize Chinese Ancient Books in the Digital Age
Wang, Linxu; Wang, Jun; Tong, Wei

The Triple Helix Interactions among Universities, Industries and Governments: Case of Climate Change Field
Xiong, Wenjing; Song, Yijia; Fu, Hui-zhen

Exploring the Information Cues of Danmaku Comments to Stimulate Users’ Affective Generation in Reaction Videos
Ye, Xujie; Zhao, Yuxiang (Chris); Li, Jinhao; Zhang, Yan; Hansen, Preben

How Are Policy Document Mentions to Academic Papers Accumulated?
Yu, Houqiang; Yao, Renfeng

AI-Based Research Tool for Large Genealogical Corpora: The Case of Jewish Communities Worldwide
Zhitomirsky-Geffet, Maayan; Suissa, Omri
Advancing LIS in iSchools: Building a Coalition To Ensure a Vibrant Future.................................................................825
Palmer, Carole L.; Bonn, Maria; Coward, Chris; Knox, Emily; Marzullo, Keith; Ndumu, Ana;
Subramaniam, Mega; Thomer, Andrea

Pathways to Positive Change: Exploring Research Engagement in Practice Contexts.........................................................829
Polkinghorne, Sarah; Bowker, Lynne; Detlor, Brian; Greenshields, Mary; Mckay, Dana

Strategies for Conducting Critical Research in Information Science by Designing Social Justice Research
Informed by Intersectionality ................................................................................................................................................................................833
Senteio, Charles; Chancellor, Reneate; Brewer, Robin; Gray, LaVerne; Threats, Megan

Global AI Initiatives: from Theory to Practice .................................................................................................................................836
Singh, Vandana; Bilal, Dania; Cox, Andrew; Chidziwisano, George Hope; Dinneen, Jesse David

Strategies for Conducting Critical Research in Information Science by Designing Social Justice Research
Informed by Intersectionality ................................................................................................................................................................................833
Senteio, Charles; Chancellor, Reneate; Brewer, Robin; Gray, LaVerne; Threats, Megan

From Data to Action: Leveraging Open Data to Drive Knowledge-Based Intelligent Governance .................................845
Wang, Fang; Zhu, Hongzhi; Wu, Yejun; He, Daqing; Liu, Xiaozhong

Digital Inequalities to Digital Inclusion in Online Learning: Viewpoints of LIS Educators Seeking
to Bridge the Disparities .................................................................................................................................................................850
Warraich, Nosheen; Caidi, Nadia; Mehra, Bharat; Ekmeckioglu, Cansu; Ali, Irfan

Information Science in Europe: Current Perspectives ...................................................................................................................853
Webber, Sheila; Aparac-Jelusic, Tatjana; Pestana, Olivia

Conceptualizing Data Behavior: Bridging Data-centric and User-centric Approaches ..................................................856
Zhang, Pengyi; Gregory, Kathleen; Yoon, Ayoung; Palmer, Carole

Alternative Events
Storytelling for Translational Research Impact...............................................................................................................................861
Gonzalez, Sarah; Liu, Ying-Hsang; Syn, Sue Yeon; Makri, Stephann; Connaway, Lynn Silipigni;
Given, Lisa M.; Hartel, Jenna; McDowell, Kate

Posters
Messages and Calls Ignored? A Survey of Four Thousand Smartphone Users on Non-Response Behavior ....866
Agarwal, Naresh Kumar

Information Sharing for Academic Purposes: A Mixed Method Investigation into the Use of Social
Networking Tools for Learning among Undergraduate Students at Kuwait University.................................................................869
Alsaeedi, Farraj

Data-Driven Decision-Making Practice in Higher Education Institutions in Ethiopia..........................................................872
Asfaw, Zelalem; Alemneh, Daniel; Jimma, Worku; Ferede, Bekalu

Zooming into the Future: Implementing Theory into Practice for Educational Crisis Times ...............................875
Ayalon, Ayelet; Aharony, Noa

Generative Artificial Intelligence (GAI) Divide: An Empirical Examination of the Micro-Macro Factors
that Predict GAI Knowledge and Use ..................................................................................................................................................878
Ball, Christopher; Huang, Kuo-Ting

Using Critical Race Theory to Inform a Multi-Session Information Literacy Workshop Series for
First-Year Students of Color .................................................................................................................................................................881
Ball, Heather

Developing Critical Information Literacy Pedagogies in the Face of Scholarly Misconduct ........................................883
Batool Shahid, Syeda Hina; Sinnamon, Luanne

Enabling Historical Thinking through Interorganizational Cooperation ..........................................................................................................................886
Bossaller, Jenny; Witt, Steven; Aparac-Jelušić, Tatjana

The COVID-19 Pandemic’s Impact on Credibility of Health Sources Among Undergraduate Students ........889
Bowen-Ziecheck, Aaron; Bartlett, Joan C.

Translating Research into Practice: Plain Language and Writing for Machine Translation Guidelines .........................892
Bowker, Lynne

Making Ends Meet in a Pandemic: African Library Initiatives During COVID-19 ..............................................................895
Bugre, Charles; Jowaisas, Chris; Young, Jason C.

From the Chairs

On behalf of the Conference Committee, please join us for the 86th Association for Information Science and Technology (ASIS&T) Annual Meeting.

We are excited that the ASIS&T Annual Meeting will return to Europe, hosted in London, one of the world’s most vibrant capital cities. We look forward to many stimulating paper presentations, workshops, and panels with lively discussions and pleasurable social occasions.

This year’s theme for our Annual Meeting is ‘Making a difference: Translating Information Research into Practice, Policy, and Action’. Information is one of the most powerful tools for achieving social justice. It plays a pivotal role in tackling crisis situations, creating robust democratic processes, over-coming social and economic disadvantage, and increasing our global assets of education, knowledge, and culture. Challenges to social justice often come first in the form of challenges to information: censorship, fake news, hollowing out of information services, and denial of access to information. Promoting the power of information to develop human happiness, equality, and wellbeing means tackling these problems and finding ways to release the transformational power of information research.

To achieve positive change, we need to consider what processes are effective in developing new ways of working with information, appreciate the challenges of translating excellent research into excellent practice and policy, and understand how to evaluate the difference we have made to the lives of others. As the premier international conference in the field, the ASIS&T Annual Meeting is a forum to assist in addressing these issues as we continue to push forward the positive contributions of information and technology. This includes the introduction of a new category of contribution for this year’s conference, that of research in practice papers to present examples of how research has been translated into practical outcomes.

We have three keynote speakers for our Annual Meeting. Sharing the opening plenary session, we have Alison Phipps and Tawona Sitholé from the University of Glasgow in Scotland. Their keynote is entitled, Librarians as Lifelines: In Praise of Critical Information Care.

Our closing plenary keynote speaker, Stuart Hamilton is Head of the Libraries Development for the Local Government Management Agency in Ireland. His keynote is entitled, If You Don’t Get It the First Time, Back Up and Try It Again (Party): How Information Research Must Be Harnessed to Improve Library Advocacy.

We are most grateful to our conference leadership team for all their insight, dedication, and hard work. Thanks to paper chairs Vivien Petras and Rebecca Reynolds, poster chairs June Abbas and Dana McKay, panels & alternative events co-chairs Alison Hicks and Alex Poole, and doctoral colloquium co-chairs Pnina Fichman and Howard Rosenbaum, we have a stimulating and inspiring programme.

We look forward to an important and exciting conference in London. We hope to see you there!
Many thanks to the 476 reviewers who completed 1,848 reviews of paper, panel, alternative event, poster, and doctoral colloquio submissions. We’d like to especially acknowledge our outstanding reviewers (marked with an *) who have been selected for a best reviewer award for papers, panels, alternative events, and posters.

ABSTRACT
The outbreak of COVID-19 posed one of the most serious threats to humanity in recent times. The rapid transmission of this virus across the globe and presence of various information imperfections (e.g., absence of information, confusing information, misinformation) made the craft of developing an effective information policy during this pandemic extremely difficult. This study has analyzed the COVID-19 information environment of Australia with an aim to understand the important features of the information flow which, in part, helped Australia to achieve one of the lowest COVID-19 test positivity rates. The findings of this study carry important implications for the design of future information policy imperatives aiming to deal with pandemics, natural catastrophes, and human-made disasters.

KEYWORDS
COVID-19; information flow; information policy.

BACKGROUND PERSPECTIVES
COVID-19 has left a far-reaching impact on people across the globe. There is no facet of our life that this virus has not left an impact on. We noticed that contrary to the past pandemics such as Spanish flu and more recently SARS, COVID-19 spread very rapidly to almost every country in the world but more importantly caused millions of people (WHO Coronavirus (COVID-19) Dashboard, n.d.) losing their lives due to this virus.

Information policy, according to Braman, (2011, p. 3), can bring society-wide constitutive effects through information creation, processing, flows, access and use. Jaeger (2007) argued that information policy can have an immense impact on the roles of information in society. Facilitated by the ubiquitous online ICTs and global interconnectivity, the role of information policy during COVID-19 pandemic became central in developing a nation’s response to this virus, in fighting misinformation and disinformation, announcing lockdowns, and in alleviating concerns about the vaccination.

The nexus between mass media, information policy, government agencies, and the Internet presents an information environment that informs every aspect of our lives. Information environment, according to Lievrouw (2000, p. 156) is created by different sources of information at the most general level which becomes highly important to individuals when they get to know the available information and find it relevant to their needs. According to Lievrouw, various institutions, including government, cultural, and business organizations, produce information, which is then shaped by media.

Media captures information about different events and then disseminates it to people. Media also play an important role in regulating and shaping information flow which arguably has been taken to a new level by social media (e.g., Aral, 2020, p. 58). In any information environment, there can be several distinct flows of information pertaining to different events. For example, information in media about weather forecasts or stock markets presents distinct flow of information. Flows of information can change public opinions, inform policy imperatives, help in relief efforts, and can raise awareness about the risks posed by a crisis. The potential impact of any information flow is shaped by factors such as frequency, volume, intensity, and speed of an information flow. In addition to the preceding factors, quality of information underpinning an information flow is also an important ingredient.

It is evident from a copious body of research that aspects such as frequency (e.g., Chatterjee, 1999), speed (e.g., Aral, 2020), volume (e.g., Knippenberg et al., 2015), intensity, and quality of information are the real substrate of any information flow. Depending on the imbalance in and/or absence of the properties of information underlying any information flow, there can be varied information imperfections that emerge and become part of an information environment. Incomplete information, misinformation, disinformation, absence of information are some of the imperfections that can arise in any information environment and can seriously impact individuals, organizations, and
even governments. These imperfections can cause what is termed as ‘information failures’ which can become a source of political debacles, adverse healthcare events, and mismanagement of natural disasters.

COVID-19 presented such a situation where massive flows of information about different aspects of this pandemic were in circulation through various media outlets, government health departments, and international organizations. However, not all of this information was helpful in making sense of this crisis and often this information led to bewilderment. There were several reports of different information imperfections (e.g., misinformation, disinformation, lack of information, too much information) in COVID-19 information flows and the result was that the efforts aiming to understand, manage and control the numerous immediate and long-term effects of this crisis were far from being comprehensive. There have been efforts to study public response to coronavirus in social media (e.g., Thelwal, 2021), issues of misinformation (e.g., Wang et al. 2021; Zhou et al. 2021) and information avoidance (e.g., Link, 2021) during this pandemic. However, our understanding of the ways in which COVID-19 information flows evolved as this pandemic progressed is sketchy. We also don’t have clear idea about the nature of changes in disseminated information as this pandemic unfolded. The answers to the preceding questions can be quite helpful in informing information policy frameworks concerned with avoiding and managing a pandemic and/or a catastrophe.

The purpose of this research is to investigate the COVID-19 information flow in a bounded context of time and place (1) to identify and explicate the factors that underpinned and shaped the information flow and (b) to draw lessons that could inform future information policy imperatives aiming to deal with pandemics, natural catastrophes, and human-made disasters.

RESEARCH METHODOLOGY
Conceptual Framework
The conceptual framework was weaved by keeping in mind the research objectives of this study. The notions of frequency, volume, speed, intensity, quality, and information environment were used to develop a conceptual lens to look at the COVID-19 information flow. To identify the sources of COVID-19 information flow, the work of Lievrouw (2000) was used to choose relevant public media news outlet and official source of information on COVID-19. The qualitative and quantitative properties of information—based on the works of Knight and Burn (2002), Savolainen (2011), and Keller and Staelin (1987)—informed our review of the news items as well as of the information disseminated by the government agency. The work of Turner and Pidgeon (1987) guided us in terms of finding instances of information failures in COVID-19 information flow.

Research Context
For this study, we decided to review the COVID information flow in Australia. There were few reasons for this choice: (1) Australia was successful—especially in the very early phases of COVID—to keep the rate of infections very low, (2) had an effective information communication during the outbreak of this virus (Hyland-Wood et al., 2021), and (3) also recorded one of the lowest per capita fatalities from COVID-19 (ourworldindata.org as cited in Bromfield & McConnell, 2021, p. 519). All of the preceding reasons allude to a highly plausible assertion that the nature of information flow during COVID-19 in Australia may have contributed in limiting the negative impacts of this virus and hence worth examining to find some lessons for future information policy imperatives concerning managing a catastrophe.

Analytical Framework
Owing to huge amounts of information about COVID-19 and the underlying aim to understand the information flow progression in the very early phase of this virus, it was important to keep the scope of this research limited to a certain time frame as well as to news outlets with vast coverage and high import. Limiting the time frame also provided us with the ability to carefully analyze the different features of COVID-19 information flow. Therefore, a time frame encompassing the first mention of COVID-19 in media till the announcement of first lockdown in Australia was chosen. One mass media news outlet ABC [Australian Broadcasting Corporation] with vast coverage was chosen. ABC news was selected because it is considered to be the top news source in terms of the volume of visits to its website (Top news sites, 2021) as well as the most trusted source of information and current affairs in Australia (Trusted news and information, 2020). For official source of information, the Australian Government Department of Health (henceforth Dept. of Health) was selected.

Content analysis was used to review the news items from the ABC news as well as the information disseminated by the Dept. of Health. The analysis focused on gaining understanding of the overall scope of information provided and to identify the main theme of each news item. Initial review of news items enabled us to ascertain the aspects of COVID-19 that were covered which then guided the development of categories (Table 1). We reviewed together the domain of each category and then undertook the first round of content analysis. After the first round of coding, we met to review the classification of news items and press releases. Minor differences were observed which were resolved through discussion and elaboration on the rational used for classifying a particular news item or a press
release in a category. These discussions ensured consistency and uniformity in coding. A debriefing session was also held at the end of coding to review the complete categorization.

</table>

Table 1. Categories and their description

In addition to the identification of main theme of each news item, it was also important to look at the frequency of news items, to map the timing of news in order to develop a better understanding of (1) when information flow about COVID-19 started, (2) when the magnitude of COVID-19 information flow started to become regular and larger, (3) why some information flows about certain aspects of this pandemic started, (4) why their magnitude...
became larger or smaller as this pandemic started to unfold, and (5) what were some of the most prevalent themes in the COVID-19 information flow. For this purpose, we mapped the (a) dates on which COVID-19 information flow started, (b) time frame during which COVID-19 information flow started to become large, (c) time frame during which volume of information reached its peak, (d) the time-lag between the first mention of COVID and the first lockdown. It was hoped that the mapping of all of the preceding elements would help us to pin down the anatomy of COVID-19 information flow.

The web archive of the ABC news (https://www.abc.net.au/news/archive/) was searched using a combination of different search terms (Table 2) and a total of 346 news items about COVID-19 were identified (Table 2). These news items appeared between 4th January, 2020 and 22nd March, 2020. Each news item was content analysed to identify its main theme as well as to ascertain the aspects of COVID covered. This review resulted in the classification of news into 12 categories (Table 2). As for the government source, the web archive of the Dept. of Health (https://www.health.gov.au/) was searched and a total of 32 news releases were found which were classified into 8 categories (Table 2).

Table 2. Information sources, search terms and categorization of news items

**AUSTRALIAN COVID-19 INFORMATION FLOW**

During the first three months of COVID-19, ABC news disseminated information quite frequently about the following aspects of this pandemic: educational 68(19.65%), economy 68(19.65%), management 67(19.36%), outbreak and spread 48(13.87%), and events 37(10.69%). Less frequent but still regularly occurring news included about travel 26(7.51%) and politics 19(5.49%). Least frequent categories included racism 1(0.29%), health workers 1(0.29%), research 3(0.87%), and resilience 4(1.16%). The news releases by the Dept. of Health focused very heavily on management 12(38%) of and education 10(31.25%) about COVID-19. There were few official releases about other aspects of COVID such as travel, economy, and events.

It took almost a month for information concerning COVID-19 to be regularly disseminated through the news. For instance, the first mention of COVID-19 in ABC news was on 4th January 2020. However, it was not until 30th January that COVID-19 started to gain regular attention in ABC. Though news appeared before 30th January as well but there were often in-between breaks of 2, 3, 5 and even more days before one would see anything about this pandemic. A somewhat similar observation was made for COVID-19 information flow coming from the Dept. of Health. The first news release identified was on 25th January, 2020 with a very regular flow of information not starting till 12th March 2020. There were news releases in-between but with intervals ranging from 2 to 7 days.
In news, since 30th January, information flow concerning this virus became distinct and regular – that is, one would see every day some news item about COVID-19. As the virus started to spread globally, so the COVID-19 information flow started to become not only frequent but also greater in its volume. So, for example, in the month of January there were 18 news items about COVID-19 whereas this number grew to 53 in February and quadrupled to 275 in March—the month in which first lockdown was announced in Australia. It was also interesting to analyze the surge in volume of information in the three weeks of March. Specifically, a very significant upward trend in the volume of information was noticed beginning the first week of March 2020 and reaching its climax in the last three days—preceeding the first lockdown—of week 3 (Figure 1).

![Figure 1. Daily totals of news items](image)

A similar surge in volume of information was also observed in the Dept. of Health data. In the days leading to first lockdown, information about ‘management’ and ‘education about this virus’ doubled in volume. It can be reasoned that information flow about COVID started to change in its nature (i.e. kinds of topics covered), frequency and quantity in public media in response to many influences including daily press conferences by government officials, information coming from international sources as well as from WHO raising alarm about this impending crisis.

It was also important to find whether the nature of COVID-19 information flow changed over the time in terms of aspects covered in the news items. It was found that five aspects of this pandemic predominated the information flow starting from the first mention of the virus till the first lockdown. These aspects included: outbreak and spread, educational, management, economy, and events. Information about two aspects ‘management,’ and ‘educational’ increased phenomenally nearing the first lockdown in March (Figure 2). The fact that ‘management’ and ‘education’ were the two most important themes in Australian COVID-19 information flow disseminated through both the most influential media outlet and the Dept. of Health possibly points to a close interaction between government’s information policy around COVID-19 and information disseminated through mass media creating an information environment which helped to create a shared understanding of an impending crisis and a response to it.
From an information quality standpoint, it can be argued that the information created and disseminated through the Dept. of Health was objective, clear, timely, re-assuring, and credible. For instance, when first case of COVID-19 was identified in the state of Victoria the statement on the Dept. of Health website (dated January 25, 2020) read “Australia has world-class health systems with processes for the identification and treatment of cases, including isolation facilities in each state and territory, these processes have been activated.” This statement was clear and re-assuring to the masses that the Australian health and quarantine systems were robust enough to deal with this crisis. The information released in many instances was based on evidence either gathered from overseas and/or from multiple sources but analyzed and interpreted by experts—all of which added to the credibility of information. An example was on January 30th 2020 when the Dept. of Health noted that

“New international evidence suggest that asymptomatic or minimally symptomatic infection can occur, and that pre-symptomatic transmission has occurred in at least one case cluster. German case cluster: It has been reported that participants at a workshop in Munich had…”

It is important to note that uncertainties that could have important implications for COVID management were officially acknowledged. For instance, on March 4th 2020 the Dept. of Health noted that they don’t have a complete picture of what was happening especially in China and Iran in terms of actual number of COVID-19 cases and went on to recommend that government should focus on domestic containment and preparedness for a very likely COVID-19 outbreak in near future. A very important juncture in the journey towards first lockdown was the release of ‘Australian Health Sector Emergency Plan’ for COVID-19 on February 18th 2020. The documentation of this plan clearly laid out the steps to be taken and was accessible in audio format, big print and in a summarized form for people with special needs. In addition to the provision of information in different formats and media, some of the key points from important official documents and announcements were extracted by the ABC news and presented to people in an easy-to-read form. For example, on March 1st 2020 ABC reported that “Australia’s [emergency response] plan outlines responses to three levels of outbreak severity—low, moderate and high.

Under the plan, this is what would happen under a worst-case scenario:

“Large gatherings cancelled, People having to work from home, Mortuary services prioritised, Aged care homes locked down, and Childcare centres closed.”

This information enabled people to have optimum amount of information available to them from a lengthy document and facilitated their thinking (e.g., Keller & Staelin, 1987) about what could happen in the case of a lockdown. This re-packaging of information helped in educating people about the control-measures and to have a groundswell of support if these measures were to become a reality.
Despite efforts to provide timely, objective, clear, and complete information there were information imperfections that emerged and impacted on the efficacy of communication in the early times of COVID-19 outbreak. For example, inconsistencies were observed between federal and state governments’ messaging about the shutdown measures (Duckett & Stobart, 2020). This inconsistency was also noted in government messaging for the healthcare sector: for instance, the Australian Medical Association in the state of New South Wales voiced frustrations on the confusing information that medical professionals were receiving from the federal government and different state health authorities. This information problem was recognized by the Chief Medical Officer who stated

“I recognise that the evolving nature of this outbreak has required public health advice to evolve rapidly with the emerging epidemiology. This has made it more challenging for people to keep it up to date and has led to some confusion and a perception of inconsistency of information / information gaps [emphasis added]. We are addressing this and will enhance communication to primary care, starting with this letter…”

In addition to issues such as ‘confusing information’, there were instances where administrative failures led to key information not being communicated to relevant authorities leading to COVID outbreaks. For example, on 19th March 2020 Ruby Princess cruise ship docked at Sydney Harbour. Out of 2700 passengers on board about a dozen tested positive but this information was not communicated to other passengers and everybody was allowed to leave the ship. This information failure made this cruise ship as one of the biggest single source of COVID infections in Australia (Coronavirus: How did Australia's Ruby Princess cruise debacle happen?, 2020).

DISCUSSION
The data analysis was revealing from many vantage points. Specifically, the analysis showed that as the COVID-19 pandemic progressed so did the information flow both in qualitative and quantitative terms. In the early days of this pandemic the information released from the public media was about ‘outbreak and spread’ and the possible impacts of this virus on the Australian economy. However, as it started becoming apparent that this virus will hit the Australian borders as well so information to educate masses about the risks of this virus and the ways to protect oneself from it was also started to appear both in the public media and through the official source.

The Dept. of Health in the very initial stages (i.e. month of January 2020) of COVID-19 started to release information primarily about assuring people that Australia has robust healthcare system and also educating them about the nature of virus and its transmission. In a similar vein, the information disseminated by the ABC news in the later part of January 2020 aimed to develop confidence among people that Australia is well prepared to deal with this virus. ABC news also used the statements of the Australian Chief Medical Officer to enhance the credibility of its reporting.

As the government started to prepare for tougher control measures, various documents were released including ‘Emergency Response Plan for Communicable Disease Incidents of National Significance: National Arrangements’ and ‘Australian Health Emergency Response Plan’ for COVID-19. In addition to these plans, the government also launched COVID-19 campaign to reach out to all Australians on a very large scale. The ‘Australian health emergency response plan’ and the campaign were released in multiple languages and also made accessible in different formats in order to be accessible and usable to people from diverse backgrounds and/or with special needs – an approach that is considered by Hyland-Wood et al. (2021) very important in making government communication effective.

There were, however, very important information imperfections present in the COVID-19 information environment both in Australia and globally. In few cases, these information imperfections resulted in what Turner and Pidgeon (1997) described as information failures with serious health and safety consequences. For example, the BBC, at the very onset of COVID-19, raised questions about the accuracy of the numbers reported in Wuhan (https://www.bbc.com/news/health-51148303). Echoing BBC, the ABC reported on 10th January 2020 that according to WHO

"More comprehensive information is required to confirm the pathogen, as well as to better understand the epidemiology of the outbreak, the clinical picture, the investigations to determine the source, modes of transmission, extent of infection, and the countermeasures implemented.”

Further affirming the lack of information about the number of COVID-19 cases, the Dept. of Health stated on March 4th 2020 that due to immense pressure on healthcare systems of Hubei (China) and Iran it is quite likely that cases with mild and asymptomatic illness were under-reported. This absence of information may have seriously impacted the ability of governments to make head-start on measures aiming to control this virus.

In addition to the issue of incomplete information, challenges such as ‘confusing information’ and ‘absence of information’ were also noticeable in Australian COVID-19 information flow especially during the weeks leading to the first lockdown. The issue of ‘confusing information’ impacted on the ability of health care professionals to
decide on how to accurately test potential COVID-19 cases. The severity of these challenges started to decrease as consensus started to emerge among various federal and state agencies about the ways to manage COVID.

Recognizing widespread misinformation and disinformation during COVID, both Dept. of Health and the public media highlighted these problems to inform people about the potential risks that such kinds of information posed to health and community welfare. Misinformation about transmission of this virus which then led to some racist attitudes towards people of Chinese descent was dealt with early on by both the Dept. of Health and the ABC news. Some other instances of misinformation including, for example, that Bill Gates created this virus, one can be protected from this virus by drinking bleach, and some imported food in Australia is infected with COVID-19 were reported in the ABC with an aim to caution people against misinformation.

It can be proposed that COVID-19 information flow in Australia—preceding the first lockdown—exhibited an anatomy where at the onset information about the spread of virus was circulated closely followed by information concerning the varied risks posed by the pandemic and then including information which was highly educational in nature. One can see a near parallel upward surge in information about ‘education’ and ‘management’ both in ABC news and in the Dept. of Health information (Figure 3). Though this near parallel relationship was more pronounced in the case of ABC. This information flow aimed at preparing masses to fully grasp the enormity as well as the risks posed by the pandemic so the people could rationalise and accept the measures which the officials were about to implement—one of the longest lockdowns in the world.

![Figure 3. Comparison of news items from Department of Health and ABC News](image)

**IMPLICATIONS FOR INFORMATION POLICY**

As information policy encompasses decisions and activities about information creation, processing, flows, access and use (Braman, 2011) so one can use analysis of an information flow within an information environment to draw lessons for future information policy initiatives and COVID-19 provided just that opportunity. Based on our analysis of the information in this study, we argue that the Australian COVID-19 information flow presents very significant lessons for information policy. Specifically, it can be stated that the Australian COVID-19 information flow through the official government source as well as through the ABC news aimed at educating and preparing public through a clear, timely, objective, and fact-based information. When certain pieces of information were not available, instead of covering that uncertainty the information released by the Dept. of Health acknowledged the gap and used the best available sources to arrive at their recommendations. Information about key documents (e.g., health emergency plan) was provided in accessible formats by the Dept. of Health and synthesized in some cases by the ABC news to help people know the most salient points of key documents and announcements. Despite all of the preceding efforts, there were still some glitches in the flow of information from the Dept. of Health to medical practitioners. The issue of confusing information not only for public but also for health care professionals in the early days leading up to lockdown made it difficult to completely comprehend the policy imperatives concerning COVID-19. In its totality, the information flow about COVID-19 in Australia primarily used educational approach starting from informing people about virus, its possible means of transmission, no. of cases overseas and—then following small transmissions of virus in Australia—to the potential serious impacts of this virus on vulnerable communities and healthcare system. This information was augmented with the possible measures that should and must be taken now
and in near future to protect all Australians from this virus. We believe that in a pandemic or a catastrophe, the information policy of a government can be informed by some of the salient features of the approach taken to COVID-19 information flow in Australia.

LIMITATIONS
It is important to keep the limitations of this study in sight when considering the findings. The data set was limited to a time frame covering the first mention of the virus in news to the first lockdown in Australia thereby omitting the time following this snapshot. Another limitation of this research was a focus on two sources of information about COVID-19 excluding other public media outlets and social media. Thirdly, due to the inherent complexity of any information environment, it is quite likely that we may have missed some factors that must have played an important role in shaping the COVID-19 information flow in Australia. Consideration of information flow in later months will be essential for developing a comprehensive understanding of COVID-19 information flow. Finally, though an effort was made to cover all news items in the two sources, it is likely that inadvertent omission of some news items may have occurred.

CONCLUSION
Information policy is an important pillar of governance but it becomes more crucial in times of pandemics, natural catastrophes, and human-made disasters. This study set out to understand the Australian COVID-19 information flow with a purpose to identify important lessons for information policy. The data from the most prominent mass media outlet and the Dept. of Health were analysed covering a period of time starting from the first mention of COVID till the first lockdown in Australia. It was found that the Australian COVID-19 information flow in this study presented an anatomy in which two aspects (educational and management) predominated both the mass media and the Dept. of Health information whereas aspects such as economy, outbreak and spread, and events also were highly visible in the mass media COVID-19 information flow. Furthermore, the information disseminated by the Dept. of Health and the ABC news was timely, clear, fact-based, and in many cases was packaged in multiple formats to be inclusive of people with special needs. There were, however, presence of different information imperfections including missing information, confusing information, conflicting information, misinformation and disinformation in the COVID-19 information flow. The overall approach taken towards COVID-19 information flow in Australia created an information environment which was educational in nature, kept people informed about various control measures, and was mostly built on information that was factual, timely, and clear. It is hoped that the findings of this study will inform the future information policy measures aiming to deal with a pandemic.

ACKNOWLEDGEMENTS
We want to acknowledge with heartfelt thanks the anonymous reviewers for their valuable feedback. We are also grateful to Sana Hanif who assisted with data collection.

FUNDING
This research was supported by a grant, under special project fund, from the Association for Information Science & Technology (ASIS&T) to the first author.

ABSTRACT
History has repeatedly shown that when it comes to healthcare, there exist significant disparities across different sub-populations. Part of this problem is challenges with access to healthcare services and providers. In recent years, we have seen solutions emerge that attempt to address this issue, namely telehealth. But little to no work has been done to glean insights into factors contributing to lower access and whether telehealth adequately supports populations that struggle with physical access issues. In this paper, we present findings from an exploratory, cross-dataset analysis of healthcare access in Virginia, USA. We conducted quantitative and qualitative analyses to determine correlations between socioeconomic factors and physical access. We found that population density significantly impacts physical access to healthcare. We also found that lower income communities in rural areas appear to be less satisfied with the quality of care and less likely to have adequate access to alternative options such as telehealth services. Our work has implications for research aimed at understanding healthcare access and practice that aims to derive solutions to close the healthcare access gap.

KEYWORDS
telehealth; healthcare; disparities; access; social computing

INTRODUCTION
The concerns around healthcare access have increased in recent years as we experienced a global pandemic that led to a surge in healthcare services needed and being administered. Historically, one of the major concerns regarding healthcare access, aside from how we define it, are the differences in healthcare access across communities and solutions that can help fill gaps in access to healthcare services. When comparing rural and urban populations, rural American populations experience significant health disparities, often characterized by higher incidences of disease, higher mortality rates, lower life expectancies, and higher rates of chronic pain (Hartley, 2004; Miller & Vasan, 2021). Risk factors for health disparities include geographic isolation, lower socioeconomic status, higher rates of health risk behaviors, limited job opportunities, and limited access to healthcare specialists and subspecialists (Hartley, 2004). Despite the numerous risk factors, access to healthcare sets the baseline for all patient encounters with the healthcare industry. When a patient cannot access their physician, receiving medical care, building relationships with their providers, and achieving overall patient wellness are all impossible.

Access to healthcare has been a matter of concern for several decades. Access is a multidimensional concept that is influenced by a wide array of factors. The National Academy of Medicine defines access to healthcare as “the timely use of personal health services to achieve the best health outcomes” (IOM, 1993). Access to care consists of four components: coverage, services, timeliness, and workforce (Access to Care, n.d.). Telehealth technologies, or digital and internet-based tools used to administer healthcare services (e.g., online patient portals, mobile applications, telemedicine) have helped improve healthcare delivery and health outcomes for low-income and underserved patients (Follen et. al, 2007). The impact of telehealth has been studied by multiple researchers; however, these studies are usually scoped to specific chronic medical conditions (Barbosa et. al, 2021). While telehealth has been shown to improve health outcomes and reduce cost for some conditions, little work has focused on if and to what extent it is closing physical access gaps and supporting all populations. Furthermore, to reap the benefits of telehealth, users must have access to sufficient bandwidth to access these services reliably.

Our work aims to provide insights that can aid policymakers in identifying sub-populations that need more attention and exploring potential solutions. Through quantitative and qualitative analyses, we mainly focus on accessibility from the Theory of Access (ToA) framework. Considering Virginians as our population of interest, we analyze the current state of accessibility by deriving the average distance and travel time using different modes of transport to nearby healthcare facilities and gauging the quality of care received using publicly available reviews. We also study the correlation between access and socioeconomic factors such as household income and analyze the potential for telehealth to improve access to healthcare. Our study aims to answer the following questions regarding healthcare access in Virginia:

RQ1: How accessible are general acute care facilities for Virginians?

RQ2: What are the correlations between socioeconomic factors and healthcare accessibility?
RQ3: To what extent can telehealth help improve access to general acute care?

RQ4: What are the differences in satisfaction with healthcare services provided?

BACKGROUND & RELATED WORK

Over the years, many researchers have studied access to healthcare, what it means, and how we can best support it. Below, we discuss previous work focused on providing theoretical foundations for defining access, investigating disparities in access, and emerging solutions.

Theory of Access & Its Applications

In 1981, Thomas and Penchansky proposed a framework, known as the Theory of Access, which states that there are five dimensions to healthcare access: affordability, accommodation, availability, accessibility and acceptability (Penchansky & Thomas, 1981). A well adopted extension of this framework includes awareness, which relates to effective dispersion of information and communication with patients (Saurman, 2015). Theory of Access defines affordability as the ratio of the cost of care and patient’s ability to pay. This encompasses their income and insurance policy. Availability is the volume of existing services and resources with respect to the population. Accommodation refers to how well the existing scheduling and allocation of resources fit the patients’ needs. Accessibility is the relationship between the location of services and the location of the patients. Studies have shown that geographic access to healthcare services leads to improved health outcomes as individuals with better access are more likely to seek preventative care. Lastly, Acceptability is the relationship between the expectations of the key stakeholders involved in the system – patients and healthcare providers. Prior studies have incorporated Theory of Access into their work in different ways. Multiple studies have used the extended version of Theory of Access, which includes awareness as a dimension (Saurman, 2015). Kang et al. conducted a qualitative study to understand challenges faced by asylum seekers and refugees in the UK in accessing healthcare using the extended ToA framework for data analysis (Kang et al. 2019). Pass et al. conducted similar analysis to identify barriers faced by older patients in rural communities with chronic illness in accessing mental health services in Iowa (Pass et al., 2019). Best et al. used it to measure access to Home and Community Based Services for individuals with mobility impairment (Best et al., 2022). AlDossary et. al partially used the Theory of Access framework (excluding acceptability and accommodation) to understand community needs to successfully plan implementation of telehealth services (AlDossary et. al, 2017).

Exploring differences in healthcare access

Access to healthcare varies between rural and urban areas. Residents of rural areas often must travel great distances to seek healthcare services. According to a study conducted by Pew Research Center, rural residents travel approximately 10.5 miles to seek primary care while urban residents only travel approximately 4.4 miles on average (Lam et al., 2018). Over the years, there has been a decline in the number of rural hospitals, and this is projected to get worse (Casey et al., 2001). By analyzing data from the National Establishment Time Series, researchers discovered that the number of healthcare facilities dropped between 2000 and 2014 across more disadvantaged neighborhoods (Tsui, 2020). The lack of availability of healthcare facilities in these areas is primarily due to the difficulties in retaining the workforce to provide these services. Insurance providers are less incentivized to support these facilities, which further contributes to the difficulties in maintaining and operating rural healthcare facilities (Douthit et al., 2017). In addition, this poses a barrier for rural residents financially to seek healthcare services. These factors, compounded with cultural factors and lack of transportation contribute to poor access to healthcare for rural communities. Lack of transportation also introduces additional barriers to seeking care, such as childcare expenses, accommodation expenses, and missing work. This can impact both urban and rural residents.

The lack of proper access to healthcare has longitudinal effects on health and well-being; however, to truly improve healthcare, researchers and practitioners must understand the facts that influence communities’ decision-making. The correlation between access to healthcare and well-being is evident in a study conducted by NCD-RisC, which shows that 55% of the population with increased body mass index (BMI) between 1985 and 2017 belonged to rural communities (NCD-RisC, 2019). Analyzing access to healthcare would not be complete without exploring the quality of care received. Some key factors that affect the quality of care include health literacy and cultural competence. Migrating from rural to urban communities also introduces additional challenges. A study conducted by Morales et. al. on a Mexican immigrant community in New Jersey found that in addition to factors that are known to have an impact on healthcare, the paper also proposes rethinking how we define access to account for socio-cultural practices that may have an impact on health outcomes. (Morales et. al, 2015).

Evaluating solutions to healthcare access disparities

COVID-19 has driven the world to adopt ways to accomplish day-to-day tasks virtually. This drove the healthcare industry to improve telehealth services. A study shows that this has helped reduce the number of no-shows for hospital appointments due to patients not having to travel (Franciosi et. al, 2021). While telehealth helps bring
healthcare services to the patient, it introduces new barriers into the system. Paperwork involved in the existing healthcare system is inefficient, disjointed, and can be tedious. Patients without sufficient technical literacy can feel more overwhelmed going through the process digitally (Lopez et al., 2018). In addition, while designing the current telehealth systems, insufficient thought was given to accounting for the 61 million people (about twice the population of Texas) suffering from one or more forms of disability. This community, in particular, is marginalized by telehealth services (Valdez et. al, 2021). Furthermore, roughly 1 in 10 residents of Virginia do not have access to a broadband connection (Internet Access in Virginia: Stats & Figures, n.d.). This poses a barrier for them to access telehealth services. Jin Chong outlined factors that create a digital divide with respect to healthcare services and found that middle-aged white women from higher income brackets with health literacy and access to broadband are more likely to seek healthcare information online (Chong, 2006). Several studies agree that being insured has an impact on access to healthcare. However, a study done on rural communities in Pennsylvania shows that it does not have an impact on their community (Maganty, 2021). Currently, there is no similar analysis for the United States. Researchers suggest that the current healthcare system can be improved by scheduling better, training physicians to provide care with less biased judgment, and by placing healthcare facilities in convenient locations. In addition, physicians need to be incentivized enough to create an influx of care providers in rural communities (Butkus et. al, 2020).

**METHODOLOGY**

As emphasized by prior work, there is a need for more research and development centered on understanding and targeting causes of healthcare disparities, such as access. In this section, we outline the approach we used to answer our research questions with data on healthcare and populations in the US state of Virginia.

**Population Sample**

We focused our analyses on data from communities and healthcare facilities in the state of Virginia. Based on a report from the Virginia Department of Health on socio-demographic characteristics, Virginia has a well-distributed population with respect to different characteristics such as age, income, gender, race and ethnicity, and educational status (VIRGINIA HIV EPIDEMIOLOGY PROFILE 2016 Virginia Socio-Demographic Characteristics, n.d.). This provides us with an opportunity to collect and analyze data from diverse and representative communities to strengthen the potential for scalable insights.

**Defining Access**

One important aspect to our study design was defining what we meant by “access” and how we would measure it. For the scope of our work, access to healthcare refers to the accessibility dimension of the Theory of Access (ToA) framework which defines accessibility as geographic access, or proximity of patients to healthcare service providers. Based on prior work (Marrone, 2007), our research focuses on the following factors that relate to geographical access: median household income, population density, and health insurance.

**Data & Sources**

Given the goal of our study, we needed access to data that gives us information on Virginia hospitals and community socioeconomic characteristics. We were unable to find a single dataset that provided all the information we needed, therefore, we curated and utilized existing datasets. The American Community Survey (ACS) is administered annually by the Census Bureau to collect community-centric data (US Census Bureau, 2018). The dataset contains social, economic, housing, and demographic data for specific geographic areas. Table 1 outlines what data we used from this survey. The Homeland Infrastructure Foundation-Level Data (HIFLD) is a collection of open datasets provided by the Department of Homeland Security that includes national geospatial data (Homeland Infrastructure Foundation-Level Data - HIFLD, n.d.). As indicated by the name of the source, this dataset provides infrastructure-related information for communities. We used this dataset for information on acute general care facilities (e.g., hospitals). The Federal Communications Commission (FCC) is an entity that regulates the various modes of communication we utilize, including broadband internet. We used the FCC’s Fixed Broadband Deployment data (Broadband Data Collection, 2021) to evaluate the ability for telehealth to support the various communities in Virginia. The HUD-USPS ZIP Crosswalk dataset is a publicly available dataset provided by the U.S. Department of Housing and Urban Development (HUD) (HUD USPS ZIP Code Crosswalk Files | HUD USER, n.d.). The goal of this dataset is to support researchers and practitioners in mapping United States Postal Service (USPS) ZIP codes to geographical data collected by the Census Bureau. Lastly, given there was no existing dataset that contained Google Reviews (either generally or specifically for healthcare facilities), we wrote a custom web scraping script to collect Virginia hospital reviews from Google left by patients and responses to their reviews.

**Data Collection & Pre-Processing**

To answer our research questions, we curated and analyzed data on the geographical distribution of acute general care facilities and socioeconomic factors that research has shown to have an impact on geographical access. We also
collected and analyzed data to evaluate telehealth's potential to reduce the effects of these barriers. The datasets used for this work are outlined in Table 1. Our final analyses center on a total of 94 Virginia facilities.

Table 1. An outline of the datasets curated for our study

To prepare our data for analysis, we first dropped duplicate records from each dataset. We focused our analyses on acute general care facilities, because they provide potential patients with access to primary care physicians. Studies have shown that better access to primary care physicians leads to fewer avoidable hospitalizations (Daly et al., 2017). Next, we calculated the haversine distance between the representative geocoordinate of each ZIP code to each acute general care facility. Using this metric, we identified nearby acute general care facilities from each ZIP code. To define nearby, we used findings from a survey conducted by Pew Research Center that included the distance to the nearest healthcare facility for the population of the United States (Lam et al., 2018). The survey found that 75% of the rural population lives within 21 miles of the nearest acute general care facility. Therefore, we defined nearby for our analysis as hospitals within a 21 miles radius from the representative geocoordinate of each ZIP code.

In addition, we calculated the travel time to nearby hospitals for each ZIP code by public transport as well as the drive time. We accomplished this using the Google Directions API, which combines Dijkstra’s and A* algorithms. Using this data, we calculated the average distance, average travel time by public transport, and average drive time for each ZIP code. The survey conducted by Pew Research Center shows that rural Americans live an average of 10.5 miles away from the nearest hospital. We used this as our threshold to identify regions in Virginia with below-average geographical access.

To gain insights into patient satisfaction, we used the Google Reviews dataset we curated. After manually validating our collected data, we found that the responses to negative reviews were just generic statements containing contact information to reach out to the hospital administration, and responses to positive reviews were just a thank you note. Therefore, we filtered our data to remove responses to reviews. We also dropped any duplicates, which left us with 27,002 reviews for 70 different hospitals. Next, as a part of our pre-processing steps, we removed non-alphabetical characters, tokenized the reviews, removed stop words, and lemmatized the tokens.

Data Analysis
To answer RQ1, we calculated the average upload speed and download speed available to each ZIP code. We first mapped the census tracts from the Fixed Broadband Deployment dataset to the ZIP codes using the HUD-USPS ZIP Crosswalk dataset and then grouped the data points by ZIP codes. To answer RQ2, we calculated Spearman’s coefficient for each factor to identify correlations between median household income, population density, being insured and the number of acute general care facilities near each ZIP code. To answer RQ3, we analyzed access to broadband internet for Virginia populations by ZIP code using both the current definition of broadband, which is 25 mbps download speed and 3 mbps upload speed (25/3), and the proposed update to 100 mbps download speed and 20 mbps upload speed (100/20). To answer RQ4, we performed sentiment analysis using an open-source model VADER (Valence Aware Dictionary and sEntiment Reasoner), which is explicitly optimized for identifying sentiments expressed on social media. VADER calculates the probability that a review is positive, negative and neutral. Using the probability measures from VADER, we classified the reviews into the following three classes: positive (reviews that reflect positive experiences), mixed (reviews that reflect a combination of positive and negative experiences), and negative (reviews that reflect negative experiences). After classifying each review, we grouped them by hospitals and determined the overall sentiment classification for each hospital. Next, we aggregated hospitals that could be accessed from each ZIP code and determined the overall sentiment for each ZIP code by finding the maximum occurring class.
RESULTS
In this section, we present the findings from our cross-dataset analysis of Virginia healthcare and telehealth access. This includes findings regarding access to healthcare (RQ1), correlations between access and socioeconomic factors (RQ2), access to telehealth services (RQ3), and satisfaction with healthcare services (RQ4).

Access to healthcare (RQ1)
Our analyses provided insights into geographic healthcare access across Virginia. With respect to access to healthcare facilities, we found that 13.18% of inhabited ZIP codes (118 out of 892) in Virginia do not have access to an acute general care facility nearby. For 68.694% of Virginia’s inhabited ZIP codes (613 out of 892), no public transportation is available that provides nearby access to acute general care facilities. On average, it takes 28.95 minutes to drive to the nearest acute general facility in Virginia and 121.66 minutes (about 2 hours) to take public transportation, where available. Figure 1 visualizes the distribution of nearby acute general healthcare facilities in Virginia. We can clearly see that while some areas of Virginia have a wealth of options for acute general healthcare (7 or more nearby), most have five or fewer nearby facilities. We also see that many areas, especially in central and western Virginia, have access to zero nearby acute general healthcare facilities. In Figure 2, we see that for communities that do not have access to nearby facilities, their commute to the nearest facility is >21 miles. This disparity is further highlighted in Figures 3 and 4, which visualize the average commute to the nearest healthcare facility. Many areas of Virginia have reasonable travel time to the nearest healthcare facility. However, our findings also indicate that the communities without nearby access must drive an average of 2-3 hours to the nearest healthcare facility. While public transportation may be an option for some, most of our findings suggest an even longer commute to nearest acute general care facilities via public transportation.

Correlations between access and socioeconomic factors (RQ2)
As shown in Table 2, we found that income, transit, and population density are strongly correlated with the number of acute general care facilities nearby in Virginia. Insurance was only moderately correlated with the number of nearby acute general care facilities. When considering distance (Table 3), we found no correlation between insurance and average distance to nearby acute general care facilities. We did, however, see some correlation between transit and average distance, though not quite a strong correlation. While we did not observe any statistically significant correlations between income, population, and proximity, we did find that some low-income areas that are densely populated have a number of acute general care facilities nearby. One example of such an area in our sample is Norfolk, VA, USA (located in eastern VA).

Access to Telehealth (RQ3)
We found a strong correlation between population density and internet speed. This also holds true for the population with below-average access to acute general care facilities. Based on our analyses, 82% of those who have below average access to a nearby acute general care facility also do not have access to broadband by its current definition (25/3). For 7.2% of those with below-average access to acute general care facilities, they also do not have access to broadband (25/3). When we conduct the same analyses with the proposed revision to the definition of broadband (100/20), we see a slight increase in the percentage of the individuals with below average access to nearby facilities that do not have access to adequate broadband internet (84%). With the proposed update (100/20), we would see an even larger increase in the percentage of those with below average geographical access that may not have access to adequate broadband internet (32.4%).

Satisfaction with Healthcare Facilities (RQ4)
Of the 27,002 reviews we analyzed, 12,470 were labeled positive, 8,737 were labeled neutral, and 5,795 were labeled negative. Table 4 summarizes the various descriptive statistics for the experiences reported in our dataset. We found that ZIP codes with a higher number of negative reviews had the lowest population and median household income, while ZIP codes with a higher number of neutral reviews had a higher population and median household income. In our dataset, the most positive reviews came from ZIP codes with the highest income and population density. We also found that while the communities within a 21 miles radius of acute general care facilities have an average internet download speed above 100 mbps, ZIP codes with a higher number of positive reviews had an average download speed of 224.73 mbps.

Threats to Validity
This study provides useful insights into factors that may affect or correlate with access to healthcare services, as well as how we might use data to drive innovation and change in technology and policy. While we took care to conduct analyses that provide valid, potentially generalizable insights, there are a few threats to the overall validity of our findings.

External validity
As we previously acknowledged, and by design, our study focused on healthcare access in the state of Virginia. While we are confident that our approach would scale to other states or regions, it is unclear to what extent our
insights generalize outside of Virginia. Our future work will use our current approach on data from other states and regions to determine how much our insights generalize. Another potential threat to the generalizability of our findings is the datasets used in our analyses. We could only use datasets that were made publicly available, therefore may not be entirely representative or complete. To mitigate this threat, we made an effort to triangulate data from as many available sources as we could find. We focused our analysis on acute general care facilities. This is of course not exhaustive of the options communities may have for acquiring healthcare services. However, given the implications of access to primary care physicians mentioned previously (Daly et al., 2017), we focused our analyses on acute general care.

**Internal Validity**

Working with unstructured data, as we did in our study, is challenging. The results of our sentiment analysis could be affected by typos in the reviews. Existing autocorrect libraries have a high time complexity and would likely not yield significantly better results. Therefore, any error in our analyses arising from typos can be considered negligible. Another potential threat is that our analysis relied heavily on data collected from the American Community Survey. Any selection/sampling/nonresponse bias in their data collection would be carried over into our analyses. Additionally, the results from our broadband analysis may be more optimistic than reality. According to the FCC’s definition, if one or more addresses within a census block receives service from a broadband provider then the entire census tract is designated as fully covered by that provider. This is particularly misleading for rural communities where a census block may represent an area up to 117 square miles (about the area of Athens, Georgia, USA) (Commonwealth Connect Plan 1 Report on Commonwealth Connect 2.0: Governor Northam’s 2020 Plan to Connect Virginia Contents, n.d.). To mitigate these potential threats, we did our due diligence to find as many relevant datasets as we could get access to for this research.

**Construct Validity**

The goal of this study was to provide insights that can inform future efforts at understanding and improving regional healthcare access. In doing so, we initially planned to evaluate health outcomes to paint a complete picture of healthcare access and its potential effects for Virginia residents. However, we could not acquire the data from the entities that collected the data to do so. In addition, our study does not consider towns from neighboring states that may have nearby health facilities for residents near the border of Virginia. Given the potential for constraints on health insurance out-of-state, we scoped our initial analyses to healthcare facilities within Virginia. Furthermore, for many Virginia residents who do not live near the border, facilities in other states are even less of an option. Despite this omission, our insights still emphasize important barriers to accessing healthcare and telehealth services within the state of Virginia.

**DISCUSSION**

Our work takes a mixed method approach to derive insights from publicly available datasets. Our approach and findings can aid researchers, policymakers, and practitioners in providing informed insights, policies, and technology. Below, we discuss how our findings can and should inform research and practice related to healthcare.

**Using Data-driven Insights for More Equitable Healthcare Access**

In our study, we curated and analyzed data to better understand healthcare and telehealth access for communities in Virginia. While our findings indicate that many portions of the state have adequate access to healthcare services (whether physical or virtual), our findings also indicate that there also exist disparities with respect to physical and virtual access to healthcare for several communities in Virginia. More specifically, we found that low-income communities may suffer the most from inadequate access to healthcare services, particularly in more rural areas, particularly in resources (broadband internet) and infrastructure (public transportation options) to decreased satisfaction with the quality of care received, our findings and prior work suggest that the current healthcare landscape may be harming historically marginalized communities the most (https://www.prb.org/wp-content/uploads/2020/11/WPFP-2015-Report-Racial-Ethnic-Divide.pdf) and that there is much work left to do before we can realize truly equitable healthcare access. However, our findings illuminate the fact that insights such as these are attainable and can be used to better inform changes to the healthcare landscape (or any domain where technology has been or is becoming critical).

Given the scoping our analyses, it may be that our findings and insights do not scale beyond the US state of Virginia. While it may seem like a negative, in reality it is likely the case that this kind of scoping is important for making insights actionable. In fact, prior studies have shown that to best support specific areas, it is important to engage with those communities to best understand the relevant assets, needs, and values (Le Dantec, 2012; Israel, 1998; Israel, 2010). By intentionally focusing data collection, curation, and analysis on communities of interest, we can begin to tackle problems locally more effectively. For example, knowing that the entire nation has broadband connectivity issues feels like a large problem that involves multiple stakeholders and numerous external factors. This makes taking action, or coming up with a reasonable solution, a seemingly insurmountable feat. Whereas
focusing on the state of Virginia, where we have a much smaller set of factors and stakeholders to consider and engage, we can more reasonably make actionable plans for improving access within the state. Building these kinds of foundations can create a domino effect; as each state (or region or community) uses data-driven insights to improve access locally, we will start to see the tides of healthcare equity shift across the country. These insights can also inform local and national policy that can help build sustainable infrastructures to support the changing landscape.

Prior works have highlighted barriers such as no access to devices or the internet (Hirko, 2020; Cortelyou-Ward, 2020; Funk, 2021). Our findings suggest that, even with access to broadband internet, more barriers may be on the horizon and that we not only need to think about the availability of broadband internet but also access to internet with adequate download and upload speeds. Telehealth has become a regular part of the healthcare system and a safeguard for healthcare access during times of high stress (e.g., COVID). Our findings suggest that without access to physical healthcare facilities, even with telehealth some communities may not have access to healthcare services. This is especially problematic for historically marginalized communities that often experience the highest disparities and co-morbidity rates (Daly et al., 2017; Churchwell et al., 2020; Lopez et al., 2021). Furthermore, our findings shed light on the potential negative impacts uninformed policy, standards, and legislation changes can have on the populations they are meant to serve. For Virginia, an increase in speed requirements for broadband access will only serve to reduce access to healthcare services. This emphasizes the value of taking data-driven, and even community-centric, approaches to decision-making.

Re-thinking & Scaling the Theory of Access

Our study, like many others, used the Theory of Access to define access as geographic distance between patients and healthcare facilities (Penchansky & Thomas, 1981). We have already seen prior work call for extensions to the framework to more accurately reflect relevant considerations (Saurman, 2015). As telehealth technologies become more prevalent and necessary in times of exorbitant circumstances, our findings suggest a need to re-define the term access and investigate to what extent the components of the existing ToA framework, and other frameworks like it, scales to the current healthcare landscape (e.g., the use of technology to provide services). This is especially true given the findings from our study indicate that explicit considerations need to be made regarding access to the necessary infrastructure for using telehealth services. Regardless of the standard (25/3 or 100/20) being considered, our analyses found that most Virginians who do not have access to a nearby healthcare facility also do not have access to adequate broadband (and in some cases have no access at all). Given these insights, it is important we explicitly investigate the varying factors that impact an individual or communities’ ability to participate in this mode of receiving healthcare. One way to do this would be to add a dimension for technological access. For example, our research defined technological access, or access to telehealth technologies, based on broadband connection speed. Prior work has also implicitly suggested other ways to think about access to telehealth services, such as device compatibility (Wootton et al., 2020), availability of internet services (Franciosi et al., 2021), and adequate accessibility features (Valdez et al., 2020). There are factors such as technical literacy that can affect both technological access and engagement (Triana et al., 2020; Kruse et al., 2020). Future research and innovations should explicitly explore ways we can expand our thinking around the various dimensions of access and how we can make use of them to ensure access for all.

CONCLUSION

This paper presents a cross-dataset analysis of healthcare and telehealth access in the state of Virginia. We investigated geographic access to acute general care facilities amongst communities across the state and found that there are many communities that do not have adequate access to nearby facilities, even when public transportation is an option. We also found mild to strong correlations between socioeconomic factors such as income and the concentration of nearby acute general healthcare facilities. When evaluating access to telehealth as a solution, we found that for many communities’ inadequate access to broadband internet may be a barrier to engaging in this mode of healthcare. We also found that low-income communities may be having less than satisfactory experiences with their healthcare providers.

ABSTRACT
Threats against electronic medical and health records are on the rise. These threats include phishing attacks, malware and ransomware, encryption blind spots, cloud threats, and most important one is the internal threat caused by gaps in the level of awareness and knowledge of the employees and health practitioner of handling sensitive healthcare data. Cyber hygiene is a term used to describe both the technical and non-technical threats. In the same way, personal hygiene practices are used to maintain one’s own health and protect against diseases, cyber hygiene security practices are important in protecting and preserving sensitive electronic health information systems. In this paper, we report on the findings of a cyber hygiene study carried out in Kuwait with the objectives of assessing the level of awareness, knowledge and experience of physicians and healthcare professionals. The study identified seven different areas or barriers that impacted the cyber hygiene and the adoption of electronic health medical records in Kuwait. The seven areas include financial barriers, time, difficulty of using technology, lack of management support, negative attitude toward the use of electronic medical records, legal and ethical issues, as well as cultural barriers. Most of the physicians interviewed lacked the awareness and basic knowledge needed to practice cyber hygiene. Most physicians were not aware of regulation or standards pertaining to the use of electronic medical records.

INTRODUCTION
The rising cost of healthcare and medical services due to growing population, aging societies, increase in life expectancy, and increase in the number of people with chronic disease and obesity is a major concern in both developing and developed nations. Advances in technology and electronic health record (EHR) systems have the potential to transform healthcare services by allowing physicians to do the right things at the right time. The recent experience with the COVID-19 pandemic highlighted the need for more efficient way of delivering health services online. EHRs make healthcare better for both doctors and patients by providing timely access to data for providing quality health care through knowledge of historical treatments. Adapting EHR technology into healthcare facilities can be challenging at first, but the result is worth the challenge.

There has been a steady increase in the adoption and implementation of EHR systems by healthcare institutions globally over the past few decades. This adoption was primarily motivated by the need for institutions to provide cheaper, better, safer, and more efficient healthcare for their patients. Research has shown that hospitals who adopted and implemented EHR or electronic medical record (EMR) systems had 3% to 4% lower mortality rates compared to those did not use or have EHR systems in place (Yanamadala et al., 2016). Furthermore, healthcare costs were reduced significantly using information systems (Ackermann, 1985; DesRoches et al., 2008). Kuwait has seen growth over the years in the use of digital health tools and information systems. Despite the progress made over the years, there are still area that are lacking.

Adoption of EHR systems in Kuwait’s healthcare has varied considerably, with only some government hospitals integrating their EHRs with other digital systems such as radiology and lab information systems, while other institutions only adopting fragments of digital solutions. This limited adoption is despite the establishment of central IT department to integrate electronic communication networks (Al-Askari, 2003; Almutairi, 2011; Al-Hazami, 2010; Alhuwail, 2019).

Research has clearly shown that EHR systems are necessary because they reduce costs and improve outcomes, ensure safety, improve service delivery, and ultimately patient satisfaction (Wager et al., 2009). Kuwait was one of the first countries in the Middle East in the 1980s that adopted information technology (IT) and the first Middle Eastern countries to have Internet services. Kuwait is known to be the third largest spender on ICT infrastructure in the region. The government established the National Accreditation Program for Hospitals (NAPH), which was developed by the Quality and Accreditation Directorate (QAD) under the Ministry of Health (Alhuwail, 2019);
Ladha-Waljee et al., 2014; Mitchel et al., 2014). The program has been an important steppingstone for the Ministry of Health’s effort in improving health information management systems.

Despite the heavy investment in ICT, Kuwait remains behind in EHR implementation and Cybersecurity readiness and adoption compared to developed nations. In this study, we investigate the barriers and factors impacting the adoption and implementation of EHR systems as well as the level of awareness, knowledge, and experiences of using EHR and practicing cyber hygiene by physicians and health care professionals in Kuwait.

**LITERATURE REVIEW**

The increased reliance on the Internet and Web Based applications has resulted in an increase in the number of cyber-attacks against various types of organizations including Electronic Health Systems (EHR). According to Nguyen-Dey (2018), EHRs have many benefits, such as centralizing a patient’s information and streamlining communication. These benefits with no doubt advance as technical advancements continue in the healthcare sector, but there is a need to ensure that patient privacy is maintained, and patients’ information is secure (CM, 2018). Along the same lines, Chaudhry et al. (2006) mentioned that “health care experts, policymakers, payers, and consumers consider health information technologies, such as EHRs and computerized provider order entry, to be critical to transforming the health care industry” (p. 742).

Ensuring EHRs are being secured and handled with precaution is because, with time, a patient’s medical record grows and contains important and private information, such as “identification, history of medical diagnosis, digital renderings of medical images, treatments, medication history, dietary habits, sexual preference, genetic information, psychological profiles, employment history, income and physicians’ subjective assessments of personality and mental state” (Appari & Johnson, 2010, p. 281). The lack of suitable security measures may result in many data breaches and allow patients to be exposed to economic threats, mental suffering, and possible social stigma, all indicating why a healthy budget must be allocated by IT stakeholders for EHR technology implementation. According to Almeida et al. (2017), “cyber hygiene initiatives aim at using cybersecurity best practices to appropriately protect and maintain systems and devices connected to the Internet” (p. 4). A major reason for users not participating in cyber hygiene behavior standards is because they do not have the right knowledge of the proper behavior that needs to be taken into consideration. Data and identity theft are usually linked to financial and reputational risks, but data and identity theft have a bigger threat to health care infrastructure and patient protection.

Many countries have laws to protect patients’ information privacy. The Health Insurance Portability and Accountability Act (HIPAA) increased awareness on the validity of protecting personal health information and introduced a regulatory framework to boost compliance; however, compliance does not usually translate into security. HIPAA safety strategies count on standard technological methods “of isolating critical data, but this recent study indicates that many attackers are bypassing these types of protections and do not require stealth techniques to do so” (Peraksis, 2014, p. 395). Magrabi et al. (2016) mentioned that concerns about data security provoked Health and Human Services (HHS) to update HIPAA and to increase security shields essential for health care providers that either contract or subcontract with business links to manage medical information.

There are specific legal requirements that hospitals and clinics must meet to ensure the security and privacy of patients’ medical information. The Internet age has increased the risk of malicious attacks against institutions EHR systems and compromise of patients’ private information because sharing of EHR has become more prevalent as data are stored in the cloud and not only patients but also hospitals and clients have adopted the use of mobile devices for EHRs (McGhin et al., 2019). Health information has become easier to access via technology between patients and their physicians, but it has also become easier to compromise. It is important for organizations to have ethics policies and proper systems in place for training and reinforcement to be conducted periodically to maintain and improve security within the organization and minimize the risk of exposure.

The level of EHR adoption in Kuwait according to Alhuwail (2018) is not on par with other countries in the west and the digital health tools and systems that are available are very limited. Despite Kuwait, being a rich country, it has no proper information governance via information management practices to have an effective digital health tools and systems. Alhuwail (2018) also identified a lack of information in regard to the challenges, gaps, and opportunities about information management performance in Kuwait’s healthcare institutions.

Alhuwail (2018) looked at EHR adoption levels in public hospitals in Kuwait, which vary significantly, and found that only two public hospitals integrated EHR with other digital systems such as radiology and laboratory information systems within their facilities. The remainder of the public hospitals applied only fragments of digital solutions that complete specific functions.

It is evident that the public hospitals in Kuwait are struggling with defining strong leadership and strategic directions for digital health informatics, that informatics education and training for hospital staff is lacking. Alhuwail (2018) stated that “analytical reports that help with real-time decision-making and long-term planning are either not
produced or not solicited” (para. 5). Moreover, it is not known how records are protected in hospitals in Kuwait, keeping in mind that privacy and security of health records is one of the highest priorities. Overall, the safety of patients’ information and making sure physicians maintain their cyber hygiene by gaining awareness through professional development events and reinforcement to avoid cyberattacks is what to look for when it comes to measuring the outcome.

Cyber hygiene resembles the concept of personal hygiene but instead of maintaining one’s own health, cyber hygiene practices are used to protect and preserve data and information generated and stored on individual and organizational systems. To date, however, there has been no consensus between organizations and experts on the definition or agreed practical meaning of cyber hygiene (European Union Agency for Network and Information Security, 2006; Vishwanath et al., 2020). Furthermore, there have been no measures for cyber hygiene, and existing research on cybersecurity in the social sciences has focused primarily on the users’ actions when it comes to security. These actions include password-related behaviors (Stanton et al., 2005) and email security related to end-user attitudes and self-beliefs (Ng et al., 2009). Egleman and Peer (2015) developed the four-dimensional Security Behavior Intentions Scale (SeBIS) that measures and evaluates the end users’ compliance and agreement with computer security advice. The measurement of such cyber safety behaviors is done by indirectly assuming that the users are attentive to these behaviors.

Current research of cyber hygiene has been conducted in the sense of hygiene viewed as a multidimensional idea with several elements that make up an individual’s hygiene and as a guideline for individuals about what to do using the example of hand washing and how to implement it (Vishwanath et al., 2020). These different views are due to contextual and cultural differences, making the definition of hygiene very broad with different meanings based on an individual’s personal understanding.

Ultimately, cyber hygiene refers to the practices that people engage in for cyber health or general behaviors for personal protection of electronic information from being compromised using routine checks and monitoring practices (Neigel et al., 2020). The definition and guidelines of cyber hygiene can be applied to a wide range of different consumers and can be molded to fit any specific professional or even cultural context.

**Methodology**

Mixed method approach was used to first identify the factors impacting the implementation and adoption of EHR in Kuwait and second, assess the level of awareness, knowledge, and experience of Kuwaiti physicians in Kuwait. A combination of content analysis methods provide higher flexibility when investigating behavioral issues and assist in understanding people opinion and attitude. Krathwohl (1998) extolled qualitative research as especially helpful for gaining with participants’ perceptions of a situation to understand their behavior. The semi structured interviews were used to collect information and drill deeper in the types of issues related to the awareness, knowledge, experiences of the participants. Semi structured interviews allowed for asking questions that explored the participants’ awareness, knowledge, experiences, behavior beliefs, and motivations in an in-depth manner.

The formulation of some of the questions were guided by the University of Michigan Public Health Institute, Ann Arbor (Mackison, 2011), this questionnaire was put together to collect information on lifestyle, behavior, social and environmental impacts that affect human health. The online questionnaire indicated that “permission has been obtained from the survey developers for unrestricted use of this survey; it may be modified or used as is without additional permission from the authors.” No permission was needed to modify any questions from it that were used in this research. The sample of 15 physicians was considered an adequate sample size because the physicians being interviewed are a homogenous group of people. According to Dworkin (2012), “an extremely large number of articles, book chapters, and books recommend guidance and suggest anywhere from 5 to 50 participants as adequate” (p. 1319). Due to the ongoing global pandemic and the current situation from COVID-19, the interviews were conducted virtually. Depending on the participant’s preference and the type of technology available to them, a combination of Zoom and WhatsApp applications were used to conduct and record the interviews. Snowball sampling method was used to recruit the physicians being interviewed.

An audio recorder was used to record the interviews while they were being conducted, after the interviews the audio content was transcribed and then coddled. Following the interviews, the recordings were transcribed verbatim for analyzing the participants’ data. When analyzing the participants’ data, specific things were looked at that included similar agreements or disagreements among the participants, as well as themes, patterns, and concepts. The interviews were conducted in the English language, translation was not required for the collected data. Data were analyzed by using NVivo (R-1) and Microsoft Excel software. Initially, all the transcripts were imported into NVivo (R-1) as separate files. In the first phase, all the transcripts were coded in NVivo (R-1). Next the frequencies and percentages were calculated in Microsoft Excel.
Validity testing was carried out to ensure the data are coded and transcribed accurately. Validity was established first by conducting a pilot study and then having an expert in the field (a physician) give their expert opinion on the questions and answers collected. The interview questions were pretested for construct validity, changes were made as needed. The interview questions were written with the CHB model in mind. Each part of the proposed model was set as a subcategory in the interview guide. Consistency was assured in the data collection by having the interview sessions recorded and transcribed verbatim. To avoid bias, the questions were read as they appeared on the guide. The physicians were not interrupted after the question has been asked.

Findings & Discussion

The search results for the systematic literature review were obtained using the following databases: (a) PubMed, (b) EBSCOhost, (c) The Cochrane Library, and (d) Google Scholar. The searches identified 202 articles from which a total of 36 full-text articles met the inclusion criteria. Exclusion criteria excluded duplicates, non-English articles, and articles not related to the topic or done in Kuwait but not directly related to EHR. According to Sampaio and Mancini (2007), the next stage was to analyze the methodological quality of the studies that were relevant with accordance to the inclusion criteria based on the quality of the methodology used and its relevance. A matrix was developed to classify the articles into categories or themes that deemed to constitute barriers and or major impeding factors. The results from the systematic review showed that the slow adoption and implementation of EHRs in Kuwait could be attributed to seven barriers identified in the 36 research articles. Figure 1 show the seven factors as well as compare the results from Kuwait with the rest of the GCC (Gulf Cooperation Council) countries.

![Figure 1. Barriers Reported in the Systematically Reviewed Studies](image)

The findings from the systematic literature review are also supported by the findings from the semi structured interviews. For example, Participant 12 stated that:

_Hospitals need to invest more in a flexible and a very reliable EHR and to also try to use a universal system, stick to one and not use different platforms which will confuse people. Have way better support and have staff available at all times because trouble shooting will arise and you should have super users which are people trained on this system available constantly at least the first year of implementation because when we did implement this and we would have issues it would take 30 minutes to one hour to get somebody to resolve a very simple issue and that does not help with the transition from paper to EHR._

Alaslawi et al. (2019) discussed the status and various trends of e-health tools in Kuwait and pointed out that different sociopolitical, financial, infrastructural, organizational, technical, and individual barriers are hindering Kuwait from implementing EHRs. Almutairi’s (2011) study was titled “A Strategic Roadmap for Achieving the Potential Benefits of Electronic Health Record System in the State of Kuwait,” and the author discussed the lag of implementation in Kuwait. The main factor causing the lag involved no clear plan for the implementation of EHRs in the country. Almutairi pointed out that the lack of clear direction, absence of staff training, and knowledge of the system have delayed the implementation of EHRs.

The results concerning awareness, knowledge and experience is rather interesting given the low adoption and implementation of EHR systems in Kuwait. Most of the physicians interviewed (80%) indicated that they worked in a medical facility that had an EHR system implemented, and the remaining (20%) physicians did not work in places with EHR implementation. From the 15 participants interviewed, only one participant was working in a place where the EHR system was fully (100%) implemented, and 20% of the participants mentioned they did not have a fully implemented system in place. Despite these numbers, more than half (67%) of the participants stated that they had
prior or current experience of working with an EHR system in their organizations and 33% did not have any experience working with an EHR system.

When physicians were asked about their willingness to participate in training others on the EHR system if needed, a little less than half (40%) were not willing to train others on the system and a small percentage (33%) were willing to participate in training other physicians on the EHR system. One of the main reasons most participants responded as not willing to train others on the system was, “I will not participate in training others since I don’t think I’m that knowledgeable to train others,” according to Participant 14. Participant 3 said, “No, I will not participate in training others I do not have the time.”

The participants who stated they were not willing to train others on the EHR system appeared to lack confidence in and knowledge about using the system. Figure 2 shows that most interviewed physicians were not confident using the EHR system in case of encountering privacy issues or cybersecurity threats. This finding reflects the lack of training the participants had during their careers.

![Figure 2. Level of Confidence](image)

When it comes to the implementation of the system, 87% of the physicians working in the hospital were not involved and only 13% were involved in the EHR system implementation. As to the various aspects of an EHR system used by a physician, the results showed that the percentage of participation was the following: (a) assessing patient information and writing notes (0%); (b) preparing the electronic charts including laboratory and radiology (7%); (c) viewing lab images and investigations of all aspects (40%); (d) inputting outpatient data, such as medical notes, treatment plan, and medications (07%); (e) reviewing patient history and diagnosis (7%); (f) logging progress notes and entry of lab orders and radiology orders and medications (7%); (g) making referral and appointments (13%); and (h) looking up prescribed medications, lab results, x-rays, and vital signs (13%). The EHR system charts were being used only by 20% of the physicians whereas 80% were not using the EHR system charts in place.

Participant 7 explained:

> We use it for ordering investigations finding the results, ordering radiology imagining and also looking up the results, and we use it for prescriptions and recently we moved, in the out-patient clinic, to writing our clinic notes on the electronic health record. It’s obviously better than paper charts because you don’t worry about losing the information, and it’s faster to get the information you need, and you don’t have to wait for the paper chart to arrive, and it’s more secure, and I feel it’s more private or confidential.

Based on the findings, more than half (60%) of the physicians were aware of the cybersecurity threats and less than half (40%) were not aware. More than half of the physicians (53%) expressed that they have no issues or concerns on the use of this system; 40% of the physicians showed concern that the system may be hacked, and patient confidential information may be stolen; and only 7% raised concerns that anybody can access patient notes and results. Participant 12 responded, “No, not really, I’m not aware of cybersecurity threats, [and I have] no privacy concerns with using EHR so far.”

Security measures adopted by different organizations to protect the access to an EHR system includes the use of antivirus programs (20% of the cases), user name and passwords (27% of the participants), and 53% of the participants were not sure about the use of security measures, as many of the physicians had the same answer as Participant 13, wo said, “I have no idea of any security measures.” The various aspects of the EHR system being used are generated from NVivo (R-1) and shown in Figure 3.
The fact that 40% of the physicians were not aware of cybersecurity issues affected their attitude and behavior toward the use of cyber hygiene. Participant 2 made this observation clear: “There is no privacy issue unless someone hacks the system.” Participant 3 said, “I’m not familiar with cybersecurity threats.”

With regards to experience and training, the semi structured interviews addressed the experience and training for EHR and cybersecurity (perceived behavioral control). Even though EHRs have been around for a while now, some physicians lack experience with technology. The number of years the participants had been using EHRs was widespread, but their work experience in years needs to be considered also.

Good training and practice build confidence when using EHRs. Physicians must be confident when dealing with EHR privacy issues and online security tools, and they should have the knowledge and training in case they face an issue and need to react swiftly. Only 2 of the 15 participants felt confident dealing with EHR privacy issues and online security tools. The most common answer among the 13 participants was typified by Participant 12: “I do not feel confident dealing with privacy issues and online security tools.”

One of the most important aspects of implementing EHRs successfully is to prepare physicians using the system in an effective and safe way. Being armed with the needed skills and knowledge of using EHRs might make the transition and implementation much easier and less stressful for EHR users. Figure 4 shows when the participants last attended a class on EHR and/or cybersecurity and where the class took place. Two participants had never attended any EHR or cybersecurity training during their careers.
An IT team should be available around the clock for support in the event the system crashes or if the physician on duty simply needs help. Also, periodical password changes for safety reasons are needed, and periodical training for all hospital staff on EHR systems was part of the recommendations. Participant 13 stated that:

*We need to train our physicians about the importance of patient privacy, as sometimes I don’t feel comfortable to go to government hospital if I have any medical issue. We need also to have good IT who knows how to deal with technical issues as many times they said we are not familiar how to deal with this issue. We also need to build more fixable system to edit the date as no modification can be done in case of wrong entry, and it will stick in [the] patient record forever.*

Clearly, experience and training lead to confidence in using the system as well as agreeing to train others on how to use the system. Having confidence is an indication of a control behavior which in return affects cyber hygiene. It was clear from Participant 4’s statement, “Yes, if I get asked and have full experience in all aspects of the electronic system at that time [I’m willing to train others].” Participant 13 said, “No, I will not participate in training”, and Participant 14 added, “No, I will not participate in training others since I don’t think I’m that knowledgeable to train others.”

Six of the 15 interviewed physicians were not aware of cybersecurity threats that could happen to EHR systems. While about half of the physicians interviewed showed no concerns about using the EHR system, the others expressed concerns about the possibility for the system to be hacked and patient confidential information may be stolen and compromised. Only one physician stated that anybody can access patient notes and results and did not believe cyberattacks would be a big problem. A major reason for users not participating in cyber hygiene behavior standards involved their lack of the right knowledge of the proper behavior that needs to be taken into consideration.

Assessing the participants’ knowledge about the security measures used at their workplace to protect from cybersecurity threats, many participants did not seem to know much about these. Participant 13 said, “I have no idea of any security measures.” Other participants seemed to lack knowledge of the security protocols or guidelines. Three participants mentioned the use of antivirus software. Four participants said username and passwords could protect against cybersecurity threats. Participant 12 stated, “I’m not aware of cybersecurity threats, [and I have] no privacy concerns with using EHR so far.” The results suggested that the major reason for users not participating in cyber hygiene behavior standards is the fact they do not have the right knowledge of the existing security measures or the cyber hygiene behavior they need to use. Maennel et al. (2018) pointed out that good password hygiene was related to training, awareness, monitoring, and motivation.

Regarding the level of awareness, knowledge, and experience with the use of cyber hygiene among physicians in Kuwait, the interviews provided insight into the participants duration of using EHRs, and their experience and training in EHR and cybersecurity. Four of the 15 interviewed physicians mentioned they had used EHRs between 2
to 5 years, and six physicians reported having 6 to 11 years of experience. Four physicians had over 13 years of experience.

Out of 15 participants, only one claimed having an actual encounter with a privacy issue or cybersecurity threat during their years of using EHRs. The level of confidence in dealing with EHR privacy issues and online security tools was surprising since 13 participants stated that they were not confident in dealing with EHR privacy issues and online security tools. Only two physicians felt confident dealing with any EHR privacy issues and online security tools.

Eight participants have had training in the last 5 years. To have a successful system, training must be part of the equation. Good training on EHRs can help physicians to be confident when using the system. Al-Azmi et al. (2009, p. 38) said, “This will help them to solve some simple computer and software related problems … which will eventually have a positive impact on the users … prior computer experience and training on the system is essential for success.”

Regarding training in the last 5 years, 67% of the physicians were involved in training, and 33% did not participate in EHR system-related training. When physicians were asked about their willingness to participate in providing training to others on the EHR system, 27% of the physicians did not give a response, 40% were not willing to train others on the system, and 33% were willing to participate in training other physicians on the EHR system. One of the main reasons most participants were not willing to train others was their lack of knowledge of the system. Participant 14 responded, “No, I will not participate in training others since I don’t think I’m that knowledgeable to train others.” Participant 3 said, “No, I will not participate in training others. I do not have the time.”

It is important to look at the work experience with EHR and cybersecurity outside Kuwait since many of the physicians in Kuwait choose to do their residencies abroad. Six participants stated they did not have any experience with EHR, and nine participants had experience using EHR systems abroad, mainly in the United States, Ireland, Canada, and Saudi Arabia. Six participants having no experience working with EHR and cybersecurity outside of Kuwait is a high number of physicians considering that EHRs have been available in many other countries.

The participants had many recommendations for Kuwait based on their current work experience. It is worth noting that 67% of the participants agreed with having a need to connect between the EHR systems using in all the hospitals in Kuwait to help with retrieving patients’ data more easily and diagnosing correctly. The 15 physicians suggested there is a huge demand for the implementation of EHRs in Kuwait. All the interviewed physicians referred to the urgency for such a system. Participant 2 spoke about its importance:

_Honestly, we would like to have this system to be applied in Kuwait. This will help all physicians, and not only radiologists, to access lots of info about the patient and lab results, and the communication between the physicians will be faster, and all the details about patient’s past medical history._

Also, the physicians’ stated clearly that there is a need for the implementation of EHRs. Participant 13 recommended the following:

_We need to train our physicians about the importance of patient privacy as sometimes I don’t feel comfortable to go to [a] government hospital if I have any medical issue. We need also to have good IT who knows how to deal with technical issues as many times they said we are not familiar how to deal with this issue. We also need to build more fixable system to edit the date as no modification can be done in case of wrong entry and it will stick in [the] patient’s record forever._

A few participants emphasized the importance of sharing information among healthcare institutions in Kuwait. It is common now in developed countries to have information shared among physicians after consent from the patients. In this regard, Participant 7 stated:

_My recommendation would be to go fully electronic, and it should be implemented at all hospitals, and it would be good if all hospitals can have a system where they can share the information with each other because every hospital has its own electronic health record, and they are not connected, and that would make it easy, because a lot of patients have follow ups at different hospitals so that would be good if they were all integrated in to one system and to obviously make sure it’s protected from hackers, which again I’m not sure if they have that in place or not._

**CONCLUSION**

The findings from this study supported and extended the earlier work by Alkhaledi et al. (2020) about the barriers to the adoption and implementation of EHRs in the GCC. The findings revealed structural and non-structural barriers to the adoption and implementation of EHR systems. Studies also showed that healthcare expenditure in the GCC region is less than the expenditure incurred in developed countries. The finding from the interviews provided...
insights and a better understanding of how physicians feel and think about the status of the EHR system they had in place at their workplace. In addition to physicians sharing their opinions and the attitudes they exhibited in terms of the norms and practices, and their perceived behavioral control toward the EHR, they also stated what needs to be done for EHRs to be successful at their workplace.

Many of the physicians did not work in places with a fully implemented EHR system, and only a few worked in places with an EHR system in place. Some worked with only components of an EHR system in place in their workplace. Results from interviews noted the lack of training for hospital staff. The lack of training and the low confidence the participants had in the EHR system explains the low number of participants willing to participate in training. This study had several limitations, one of the main limitations was that the study was conducted during the pandemic, so meeting physicians face to face was difficult. Physicians were extremely busy during the pandemic, which affected access to and the availability of physicians for participating in the interviews. The study was also delimited to Kuwaiti nationals working in Kuwaiti hospitals. Kuwait has a large working expat population, so limiting the participants by nationality could affect the generalizability of the findings. Another limitation was level of exposure. Not all participants had the opportunity to do their residencies abroad or go for training.

The data generated from this study can aid in creating awareness and, hopefully, lead to development plans by the Ministry of Health to encourage and convince physicians to practice good cyber hygiene. The recommendations made by physicians in this study serve as a call for action to develop awareness and training plans to educate physicians and healthcare professionals about the importance of practicing cyber hygiene. It is hoped that this research can represent the beginning of ongoing research regarding the barriers to using EHR systems since few studies have addressed the awareness, knowledge, and practice of cyber hygiene in Kuwait.

The results from this study concerning cyber hygiene by physicians can help the Ministry of Health create better guidelines and standards for physicians to access and share patients’ information and to inform policymakers to put in place a policy similar to HIPAA to ensure the protection of patient information. I hope that this research represents the beginning of ongoing research regarding the socioeconomic barriers to adopting and implementing electronic healthcare systems because Kuwait has the resources to make such implementation possible.

ABSTRACT
Patron-perpetrated sexual harassment (PPSH) is a form of gender-based violence and a pervasive problem in libraries. However, contending with PPSH requires the performance of emotional labour by library workers because of workplace cultures and professional values that prioritize patron and institutional comfort. To better understand library workers’ emotional labour as they respond to PPSH, we analyzed 510 survey responses where participants shared their experiences of, their responses to, and feelings about, PPSH. Three responsive strategies emerged: acceptance, indirect refusal, or direct refusal. Overwhelmingly, library workers reported negative emotions about the incidents. Despite these negative feelings, library workers consistently responded to PPSH by performing emotional labour that upheld “polite and professional” values. Our findings raise concerning questions for the field of library and information studies about the implicit and explicit expectations placed on library workers to perform emotional labour in response to PPSH, particularly within the context of a feminized profession and with the knowledge that PPSH harms library workers. Our goal is to support library workers and their institutions to “find a way to say ‘no’” to gender-based violence in the workplace.

KEYWORDS
workplace sexual harassment, emotional labour, library labour

INTRODUCTION
I love being a public librarian, but I believe the library profession does not take seriously the concerns of women regarding sexual harassment. We are almost constantly subjected to people making inappropriate comments and coming on to us without being empowered to handle it. The helpfulness ethic is so strong, and the fact that we are a profession traditionally filled with women, means that we are supposed to just smile and be nice.

Patron-perpetrated sexual harassment (PPSH), the sexual harassment of library workers by the very patrons they endeavour to support, is a form of gender-based violence and a serious problem for folks who work in libraries. Responding to sexual harassment is always challenging but can be even more so within library workplace contexts where “the customer is always right” and where the possibility of sexual harassment is always present. This paper focuses on how emotional labour is performed by library workers when they respond to experiences of sexual harassment. Emotional labour is a feminist concept that understands that the management of feelings and public facial and bodily display is performed by workers in ways that reflect institutional values and in exchange for wages (Hochschild, 1983). The concept of emotional labour is highly relevant to understanding the gendered nature of library work because it centres the feminized labour context in which librarianship occurs and because it accounts for and values this significant type of labour, so frequently performed by folks working in libraries.

To better understand how emotional labour is performed by library workers as a response to their experiences of PPSH, we asked library workers from across Canada to describe their experiences of PPSH, how they responded to PPSH incidents, and to describe how those incidents made them feel. Drawing from this data, we determined that multiple forms of emotional labour are frequently performed by library workers to respond to and manage harassing patrons. As a concept attuned to both library workers’ thoughts and actions, emotional labour provides us with a vocabulary to see and understand the complexity of library workers’ shifting responses to sexual harassment. It offers a way to examine library workers’ complex and sometimes painful experiences even when, on the surface, library workers react minimally and/or respond “professionally” and in alignment with their employers’ and/or Library and Information Studies (LIS) values. Understanding the distinction between what is performed as emotional labour and how library workers actually feel about their experiences of sexual harassment encourages us to look for and examine how library workers manage discomfort, uncertainty, fear, anger, and contradictory feelings about being sexually harassed as they also uphold and enact workplace and professional values. Library workers are often constrained by workplace expectations that encourage them to “find a way to say ‘yes’” to all patrons at all times. In this paper we argue that PPSH is a form of gender-based violence. Effective strategies designed to counter it must acknowledge the significant harm it creates for library workers when they endure it and when they respond...
to it in ways that do not centre their humanity or workplace rights. It is not only the responsibility of the individual library worker, but all of us, to support library workers and their institutions, to find a way to say “no.”

**LITERATURE REVIEW**

**Patron-perpetrated sexual harassment**

Patron-perpetrated sexual harassment (PPSH) is a form of workplace sexual harassment where workers are harassed by third parties, such as customers or clients, while doing their jobs. Part II of the *Canada Labour Code* defines “harassment and violence” as “any action, conduct or comment, including of a sexual nature, that can reasonably be expected to cause offense, humiliation or other physical or psychological injury or illness to an employee, including any prescribed action, conduct or comment” (Government of Canada, 2019). Particularly vulnerable to workplace sexual harassment are undergraduate and young workers, people of colour, and members of the LGBTQ2SIA+ community who experience intersecting forms of racialized and gendered oppression (Fineran 2015; Martin 2015). Within libraries, library workers are frequently harassed by the patrons that they serve. Although it is well known that workplace sexual harassment proliferates in feminized and service or care-oriented occupations, very little attention to this issue has been paid within Library and Information Studies. We recently conducted a Canadian survey of over 500 library employees working predominantly in public libraries that indicates that only 7% of participants have never been sexually harassed at work (Oliphant, Allard, Lieu, & Mallach, 2021). PPSH happens in-person, over the phone, online, outside of the workplace, and in every corner of the library. Library workers contend with different types of harassment ranging from being told inappropriate “jokes” to being asked out on dates to being stalked, touched, yelled at, and sexually assaulted. All library workers from library pages to CEOs are vulnerable to PPSH. However, our survey results indicated that library workers who are cis and transgender women and non-binary folks, younger (18-39 years old), and in public-facing positions experience PPSH most often. The same survey also suggests that, for a variety of complex reasons, library workers often do not report sexual harassment to their institutions. Some of the reasons that library workers don’t report harassment include the following: they feel that their experiences are not believed by their employers; they think that the incident was not serious enough to report, and; they fear negative professional consequences from their employer (Oliphant, Allard, & Lieu, 2023).

Within the context of academic librarianship, similarly alarming findings from two recent surveys are emerging (Barr-Walker et al., 2021; Benjes-Small et al., 2021). For example, a survey of non-student library employees of the University of California, San Francisco conducted by Barr-Walker et al. found that “Out of 579 respondents, 54% experienced and/or observed sexual harassment at work” (2021, p. 237). More broadly but certainly related, recent studies about patron violence in libraries also demonstrate that physical violence from patrons towards staff is common (Stevenson, 2022). In fact, the American Library Association recently released a statement condemning violence in libraries (ALA, 2022). Together, these studies paint a sobering picture of ongoing and frequently experienced workplace and gender-based violence directed towards library staff at their jobs.

**Emotional Labour**

Introduced by Arlie Russell Hochschild in 1983, emotional labour is a feminist concept often discussed in tandem with workplace sexual harassment (Kensbock et al., 2015; Williams, 2003). Hochschild defines “emotional labor to mean the management of feeling to create a publicly observable facial and bodily display; emotional labor is sold for a wage and therefore has exchange value” (Hochschild, 1983, p. 7). In other words, emotional labour is the paid work of regulating one’s own emotions and/or performing specific “sanctioned” emotions in the workplace in order to manage the feelings and experiences of customers/patrons/patients. In the context of feminized fields, such as service work and the “caring professions”, emotional labour theory posits that when interacting with patrons, (typically) cis gender women workers are expected to suppress and manage their emotions in the interest of satisfying their job requirements to provide good customer service and care (Forseth, 2005; Hochschild, 1983). Sanctioned emotional expressions in these contexts often include such emotions as friendliness, kindness, interest, accommodation, caring, and an otherwise full embodiment of the expression “the customer is always right.”

Related research demonstrates that performing emotional labour within the context of feminized fields including service, retail, and “caring” work, often invites sexual harassment and, conversely, is used as a coping strategy to manage sexual harassment (Good & Cooper, 2016; Kensbock et al., 2015; Virkki, 2008, Williams, 2003). For example, research about the restaurant and bar server population demonstrates that male customers often take liberties or assume that they are entitled to the bodies of their servers because staff are being nice to them (Good & Cooper, 2016). In these instances, friendliness or kindness is read as sexual interest and male entitlement takes precedence over women’s working conditions. On the other hand, feminist scholars also suggest that cis gender women employed in service and care work frequently perform emotional labour as a means to pacify aggressive customers and prevent violence and sexual advances—exchanging “niceness and empathy for non-violent treatment” (Good & Cooper, 2016; Kensbock et al., 2015; Virkki, 2008, p. 86). Indeed, the performance of emotional labour has been found to be especially onerous on and detrimental to employees experiencing sexual
harassment, who must “weigh up their feelings of being personally uncomfortable with the emotional labour requirements of the work to offer friendly, personalized customer service” (Good & Cooper, 2016, p. 462; Williams, 2003). Through the process of performing the caring and “service with a smile” inherent in service related job expectations, it sometimes becomes difficult for employees to recognize what is not “part of the job.” Service work emotional labour expectations create a workplace setting for employees that “blur[s] the lines between managing customer behaviour that is expected as part of the job, and dealing with inappropriate behaviour that could be considered sexual harassment” (Good & Cooper, 2016, p. 450). In addition to being (privately) upset with perpetrators of sexual harassment, performing emotional labour in the face of sexual harassment can make employees feel bad about their jobs, their employers, and themselves.

Importantly, from a management perspective, emotional labour also refers to “the act of expressing organizationally desired emotions during service transactions” (Morris & Feldman, 1996, p. 987). These are the emotional expressions that support the belief systems of the organization. Indeed, within specific workplaces, “management often sets rules about how employees should feel and specifically about how they should express their feelings” (Bright, 2018, p. 29). It is thus important to consider what desired emotions and related institutional values are expressed when library workers perform emotional labour in their patron interactions. More broadly, librarianship specific values and ideologies inform and impact the ways that library work is understood and performed. Service expectations of inclusion and universal access to information are identified by ALA as core values of librarianship, solidifying the rights of patrons, often at the expense of employees. For example, the Reference and User Services Association (RUSA) guidelines articulate what “good” reference service should look like which prioritizes the performance of emotional labor by library workers (Emmehainz, Pappas, & Seale, 2017). Similarly, Hicks and VanScoy (2019) note how RUSA and other core competency documents describe “appropriate” professional behaviors from the perspective of patrons, not library workers. Encoded in their professional guidelines, standards, and competencies as part of their professional identity and practice, library workers—like other care and service workers—are often encouraged to provide “service with a smile” and place the needs of patrons over their own. Although library workers are not specifically told to tolerate and endure PPSH (though our survey findings suggest this is sometimes implied by some employers), these aspects of the culture of librarianship make it difficult to label and confront issues like sexual harassment.

The concept of emotional labour has been increasingly taken up within LIS to examine a variety of facets of librarianship, with an emphasis on circulation (Sheih, 2013), library instruction (Julien & Genuis, 2009) and particularly reference services (Bright, 2018; Matteson & Miller, 2012, 2013; 2014; Shuler & Morgan, 2013). What these studies have in common is a recognition that folks who do public facing and service-oriented jobs in libraries are encouraged and/or often feel compelled to manage their own difficult emotions, to effectively perform aspects of their work that involve patron interactions. Much of this literature explores both the challenges and (sometimes) opportunities inherent in jobs defined by high emotional labour expectations (Matteson & Miller, 2012, 2013; 2014; Shuler & Morgan, 2013). Helpfully, this literature acknowledges that there is indeed pressure within librarianship to perform employment encouraged emotions. This work also explores the personal tensions that arise for individuals who must perform emotions that they don’t themselves feel (Julien & Genuis, 2009; Matteson & Miller, 2012, 2013; 2014; Shuler & Morgan, 2013). An important element of this literature are the recommendations aimed at individuals and workplaces to mitigate some of the challenges of engaging in emotional labour such as employing “coping strategies such as taking breaks away from the desk (or at least mental vacations), admitting the hurt, deep breathing, careful listening, and talking to a trusted friend or colleague to help let go of the problem” (Matteson & Miller, 2013; Schuler & Morgan, 2013, p. 122).

As noted by Bright (2018), what much of this literature fails to acknowledge is the gendered and racialized context that shapes power relations within the library. For example, feminized labour conditions that lead to high rates of workplace sexual harassment makes it more than just unpleasant, but also dangerous and harmful, to perform emotional labour during specific interactions such as when PPSH is occurring. This literature thus fails to problematize what should not be part of the job and/or consider when emotional labour should not be a job expectation.

METHOD

This paper is part of a larger research project that applies an intersectional feminist anti-violence theoretical framework to identify and document, understand, and resist PPSH in libraries (Allard, Lieu, & Oliphant, 2020; Oliphant, Allard, Lieu, & Mallach, 2021). In 2021 we conducted a national survey in Canada, soliciting responses from library workers (including librarians, supervisors, library assistants, pages, etc.) working at all types of libraries. Participant were recruited through provincial professional library listservs. We asked participants about their experiences with workplace PPSH as well as the related policies, training, and reporting mechanisms in place at their jobs. We received 505 valid responses. Employing a trauma-informed approach, our survey did not ask participants explicitly about extreme sexual violence though such incidents were shared by participants. All
participants were also provided with telephone support resources at the end of the survey. This paper focuses explicitly on participants’ feelings and responses to their experiences of sexual harassment during or immediately after harassment has occurred and is guided by the following research questions:

1) How do library workers respond to sexual harassment?
2) In what ways do library workers perform emotional labour when they are being sexually harassed?

Data from the survey questions were analyzed thematically to identify and code library workers’ responses to and feelings about their experiences with PPSH. Each survey participant was asked to describe in detail up to three PPSH incidents of their choice. A number of follow up questions about each incident elaborate participants’ responses. We used inductive qualitative analysis to analyze 510 incidents of PPSH that our participants selected to share, specifically analyzing the following survey questions about each incident for this paper: (1) Please describe or expand on one of your experiences of patron-perpetrated sexual harassment while working at the library; (2) How did you respond during the incident?; and (3) How did this incident make you feel? We also drew from other long answer survey questions as appropriate to analyze our data.

Although we received a large number of responses to our survey that clearly indicate that PPSH proliferates and is a significant problem in libraries, we cannot generalize or universalize our findings. However, clear themes emerged from our data regarding how participants responded to PPSH. Our participants were overwhelmingly consistent in describing their negative feelings about PPSH incidents. What became obvious in our early inductive analysis was that the way that participants responded to patrons during their experiences of PPSH did not match the way that they actually felt about what they were experiencing. Furthermore, when reflecting on their experiences, participants often expressed a great deal of mixed emotions and regret about their own responses to perpetrators and how it made them feel about themselves, their jobs, and their workplaces. We thus examined our findings through the lens of emotional labour by identifying participant expressions of emotional labour across participant response themes of acceptance of PPSH, indirect refusal of PPSH, and direct refusal of PPSH. How participants felt about PPSH incidents were also coded for emotions, counted, and then grouped by theme.

FINDINGS
This paper focuses explicitly on participants’ emotions and responses to their harassers during incidents of PPSH. It is important to acknowledge the institutional context within which PPSH occurs and is responded to. For example, responses to PPSH often include interactions with co-workers, managers, and the institution itself, sometimes through harassment reporting mechanisms. Participants also often informally discussed the incident with managers and supervisors after the fact. This paper does not address any secondary or institutional responses to PPSH. Instead we focus solely on the emotional labour performed by library workers when PPSH occurs.

Participant responses to PPSH
Workplace sexual harassment, by its very definition is unwanted and causes offense and/or humiliation. Almost all experiences of workplace sexual harassment reported in this survey involved some exertion of emotional labour by survey participants. In this study, participants responded to PPSH with calm, politeness, and professionalism, despite regularly feeling uncomfortable, fearful, angry, or embarrassed. Even when participants ignored or said nothing in response to harassment, they felt and endured the slight. Below, we describe how participant responses to sexual harassment can be broadly divided into 3 categories: (1) acceptance, (2) indirect refusal, and (3) direct refusal. In the categories of indirect and direct refusal, participants intervened in or responded to being harassed using a variety of active and passive oppositional strategies. In the category of acceptance, participants accepted or ignored the harassment, often out of fear of reprisal from the harasser, their employer, or both. Each response type is briefly described followed by a discussion of the emotional labour embedded within it.

Acceptance of PPSH
We use the term acceptance of sexual harassing behaviours to describe when a library worker is sexually harassed and chooses not to respond at all to their harassment or harasser. This can include ignoring the incident entirely. In some cases, it also includes appearing to consent or “go along with” harassing behaviours, either directly or indirectly. Examples of “going along with” harassment in this study include giving a patron a phone number after being pressured to do so, accepting unwanted gifts, or laughing at sexist or racist jokes that participants didn’t think were appropriate. The following quotations represent examples of acceptance responses to PPSH shared by participants:

Men will call me hunny, dear sweetheart, etc. Sometimes they hope to get better service. I just ignore the comments. It's better to not engage with them.

While I was working in the stacks (alone and relatively far from other library staff), a male patron struck up a conversation with me about me and my life. He was very polite, but clearly too interested in personal details. Eventually he asked for my contact information, which I did actually say no to and he left. I was 19
practices that strive to citing library rules to encourage appropriate library conduct. These verbal strategies are rooted in emotional labour

In the examples provided above, participants gently and politely redirect patrons back to library matters while also

The emotional labour in these examples is the work of remaining silent in the face of personal offense and injury. It is important to note that sometimes acceptance occurred because the participant was comfortable with or perhaps indifferent to the interaction, even though it was considered generally unwanted behaviour. This typically occurred during “minor” PPSH examples such as being leered at or called a pet name such as honey or sweetheart. Acceptance was also sometimes motivated by participants’ uncertainty about how to respond “appropriately” at work and within the constraints of professional library practice. Indeed, in the absence of clear guidelines about how to respond to sexual harassment at work, many library workers identified struggling to know what to do. As seen in the examples above, this sometimes resulted in doing nothing. Fear for participants’ or other patrons’ safety also sometimes resulted in accepting sexual harassment. This finding aligns with feminist research that recognizes that emotional labour is often performed to pacify aggressive customers and prevent violence and sexual advances (Good & Cooper, 2016; Kensbock et al., 2015; Virkki, 2008). Finally, the negative emotional consequences of participant silence is made clear when a participant describes the uncertainty and tension that they still feel in their own handling of a PPSH incident: “I still wonder why I acted like it was okay for him to open these pictures and leer at me to see how I reacted.”

**Indirect refusal of PPSH**

We use the term indirect refusal of sexual harassing behaviours to describe when a library worker did not directly counter or confront the PPSH to which they were being subjected; instead they used indirect or passive means to respond to, redirect, or withdraw from the situation. When participants engage in passive and indirect refusal of sexual harassment, they are working to end the interaction without directly confronting the patron about their harassing behaviours. The strategies under this umbrella were the mostly commonly employed strategies by participants across all forms of sexual harassment. These strategies are far ranging, creative, sophisticated, and include the following actions: (1) refusing to respond to inappropriate patron questions or comments; (2) redirecting the conversation back to library matters; (3) restating library rules and policies; (4) refusing requests for dates by telling the patron they have a boyfriend (but not saying no to the request directly); (5) moving away from the patron and/or creating space between the library worker and patron and/or leaving the situation; (6) asking colleagues to step in during an interaction, and; (7) [over the longer term] changing specific workplace practices and routines such as changing route home, eating lunch in a different location, and dressing differently or changing one’s appearance at work. The following quotations represent examples of indirect responses to PPSH shared by participants:

Patron came to the library almost daily over a period of a few months and would stand by the desk and talk to me. He would wait for other patrons to leave and continue conversations. I would often have to go to the workroom to get away. Asked me to go on a date several times. Tried to be polite and professional. Asked him if he needed help finding materials.

Over the course of several weeks, a man kept making inappropriate comments to me starting with mild comments and gradually increasing to comments such as ‘You are smiling because of me!’ or ‘Now you’re flirting with me!’ when I was trying to assist him with his inquiry. It got to the point where I tried to avoid him whenever he was in the library. I either ignored his comments or responded with ‘I smile at all customers.’

A patron I was helping at Customer Service kept wanting to shake my hand over and over but would not let go of my hand and caressed it with their other hand. I felt conflicted—I wanted to be friendly since he was a newcomer to Canada but I also didn’t want to touch this person. It made me feel very uncomfortable. This patron also asked me out for coffee as a way to ‘thank me’ for my help. I declined politely but he was very persistent. I tried to redirect the subject to the topic with which he needed help and told him that staff aren’t permitted to accept gifts for doing their job.

In the examples provided above, participants gently and politely redirect patrons back to library matters while also citing library rules to encourage appropriate library conduct. These verbal strategies are rooted in emotional labour practices that strive to persuade the patron to change their behaviour. The verbal strategies noted in the examples are
one tactic, among multiple strategies such as ignoring or walking away from the patron, that are used to maintain the comfort of the patron while the library worker uses a host of techniques and strategies to change themselves and their environments to subtly protect themselves and end the harassment without directly challenging the patron. The main difference between this category and the former, acceptance of sexually harassing behaviours, is that when library workers accept harassment they do not counter or resist the harassment at all. Here, resistance occurs but it doesn’t challenge the patron directly nor does it significantly imply that anything inappropriate has occurred. In other words, the library service value system that “the customer is always right” is maintained. Participants often stated that they enacted indirect refusal strategies because they believed that they were following appropriate “polite and professional” customer service practices required of their job. Similar to the acceptance of sexually harassing behaviours, participants often used these indirect approaches out of fear of both patron and/or employer retaliation.

Of note, multiple participants expressed mixed feelings and/or regret about remaining silent or using indirect refusal techniques in their reflections about their experiences of PPSH. This regret is described here as an expression of emotive dissonance, a concept developed by Hoschild (1983) and connected to emotional labour. Defined by Bright as “the strain of maintaining incongruent expressions and feelings of emotion” (2018, p. 169), emotive dissonance is the inner conflict experienced by folks as they navigate and/or reconcile specific expectations of emotional labour and their own, sometimes competing, emotions and desires. In our findings, participants regularly second guessed their own decisions and/or expressed regret about how they handled or felt that they needed to handle a PPSH response. The following quotation is an example of regret, an expression of emotive dissonance, shared by a participant:

A customer repeatedly asked if I would come to his house to help him learn English. He said he was new to America, and didn't know how to talk well and thought talking to a "pretty girl" would help him. I declined the offer. He offered to pay me. I declined again. We went back and forth, him refusing to accept no as an answer, me continuing to politely decline. After I had ended the interaction and gone into the back, he asked a co-worker for my contact information. I told him no, stood my ground, but did not insist that he stop asking. I wish I had done that differently.

In this example, the participant expresses regret that they didn’t say no more directly to their harasser. Identifying examples of emotive dissonance reveals how participants negotiate the tension between what they think is professionally expected of them in responding to sexual harassment and what they would rather do/wish they had done in response to their experiences of PPSH. It thus reveals how participants’ make sense of and navigate the complex intersection of professional values, feminized labour, and emotional labour in library work.

**Direct refusal of PPSH**

We use the term direct refusal of sexual harassing behaviours to describe when a library worker directly counters or confronts a patron who is sexually harassing them, indicating to that patron that the sexually harassing behaviour is inappropriate and/or that it is to stop. In other words, the library worker says no. While there are multiple examples of direct refusal within our study findings, it is nonetheless the most uncommonly used response to PPSH. Indeed, participants were discerning in their use of this strategy, often using it only when incidents were deemed very serious such as when harassing incidents escalated and/or felt threatening. The following quotations represent examples of direct refusal responses to PPSH:

Patron told me to smile and that it was my ‘job to make him feel better.’ Told him it was inappropriate and that it was my job to help him with research.

A patron asked a reference question, but it was clear that he was trying to stand too close to me, and he kept asking if library employees were allowed to talk to people. I kept trying to move away from him, but he kept moving closer and then tried to give me his phone number, but I refused to take it. He got angry that I was being ‘standoffish’ and then came back the next day to berate me for taking his intentions the wrong way and that I was being too unfriendly. The first day, I was very firm about telling him that I could help him with library questions but I wasn't taking his phone number, and the second day when he came back to berate me, I cut him off halfway through his sentence, and told him that everything about him made me uncomfortable, I had no interest in any kind of a relationship with him, I was not answering personal questions from him, and I wasn't going to discuss this again. I felt EMPOWERED. I don't know that I've ever said anything that made me feel so in control. He immediately left after I gave him an unequivocal ‘no.’

A patron threatened to rape me behind the library. I was alone in the back parking lot of the library with said patron (who was illegally parked). I explained that this behavior was unacceptable, took his license plate and said I was calling the police.
Direct refusal does not privilege or maintain the comfort of the patron in the same way as do acceptance and indirect refusal. Instead, participants clearly articulate their wishes (and legal workplace rights!) not to be harassed in the workplace. However, it should be noted that these responses are still typically delivered in a polite and professional manner (which can itself be challenging to do if one is scared or angry) and is therefore still defined as an expression of emotional labour. Perhaps even more telling, older participants who had worked in libraries for longer, and those in a supervisory or librarian role were more likely to enact direct refusal strategies. Sometimes they described dealing with patrons directly, especially on behalf of staff they were supervising, as part of their job responsibilities. This suggests that a combination of experience, workplace authority, and job security empowered these participants to respond directly to PPSH. Indeed, participants were more likely to respond to PPSH with direct refusal when they felt supported by their workplace.

**Participants’ actual emotions about their experiences of PPSH**

Although participants responded to sexual harassment with a variety of (almost always) polite and professional strategies that often centred the comfort of the patron, survey participants *almost universally* expressed negative emotions about their PPSH encounters. Keywords shared by participants in response to the survey question, “How did this incident make you feel?” are presented below to underline the fact that PPSH almost always created a context where emotional labour was necessary to bridge the divide between participants’ actual emotions and their beliefs about how they *should* respond based on their interpretation of their workplaces’ beliefs and practices.

Table 1. Survey participants’ commonly identified negative emotions following experiences of PPSH

The table above reflects the most cited keywords participants used to describe their emotions following experiences of PPSH. The categories are not mutually exclusive. For example, feeling unsafe can be related to fear, anger, or suffering. We ascribed the emotions or feelings to one category only in order to avoid duplicate counts of the feeling or emotion. Keywords expressing negative emotions were divided up into five broad themes: “Not in control”, fear and submission, suffering, self-recrimination, and anger/irritation. Keywords that were neutral or positive were also identified but not sub-divided. Overwhelmingly, negative emotions were identified 836 unique times while neutral or positive emotions were only identified 10 times. Of note, the term uncomfortable was used 139 times, angry was used 62 times, and unsafe or scared together totalled 83 citations. The “Not in control” theme was identified when
the library worker was not in control of the situation and where they felt the patron or institution held control over them. Expressed emotions included feeling cornered, dirty, horrified, hunted, trapped, and degraded. Emotions identified in the fear and submission theme included feeling afraid, fearful, shaken, terrified, uneasy, worried and many others. The theme of Suffering included emotions such as awful, disrespected, hurt, icky, isolated, sick, stressed, and worthless. Self-recrimination included emotions such as feeling humiliated, insecure, stupid, foolish, incompetent, young, and unimportant. Terms identified as part of the anger/irritation theme included incredulous, mad, outraged, shocked, surprised, wary, resentful, startled, repulsed, and on guard. These emotions were often directed towards the perpetrator but also sometimes the self, as well as co-workers or employers who didn’t adequately support the participant at the time of harassment or afterwards. Only 10 neutral or positive emotions were identified including feeling flattered, unsurprised, empowered, and fine.

Further analysis of emotion themes and keywords is warranted to more fully understand the impacts of PPSH on library workers but is beyond the scope of this paper. Here we acknowledge the wide range of complex emotions expressed by participants and directed at the perpetrator, employer, and often, the self. Indeed, as our data clearly indicates, library workers almost always responded to harassment in ways that were in stark contradiction to their own negative feelings about the PPSH experience (i.e. acceptance of PPSH and indirect refusal). It is telling that participants described their emotions as uncomfortable 139 times, yet the most frequently used response to PPSH, indirect refusal, centres the comfort of the sexually harassing patron as a central tenet of this response type. Perhaps most importantly, this table clearly demonstrates how bad it feels to be sexually harassed at work.

DISCUSSION AND CONCLUSION

An important finding of this research is that participants demonstrated a broad range of strategies and interventions to address PPSH that often relied on expressions of emotional labour. Library workers almost always responded to harassment in ways that upheld workplace and professional values of politeness and professionalism and were in stark contradiction to their own feelings about the PPSH experience. Emotional labour was present in all three types of participant responses to PPSH—acceptance, indirect refusal, and direct refusal. The most frequent and most typical responses to PPSH were acceptance and indirect refusal, strategies that have high levels of emotional labour embedded within them. These approaches maintain the comfort and authority of the patron even as he engages in behaviours that are, at best, not appropriate, and at worst, harmful acts of sexual violence. It should also be noted that even when library workers directly refuse PPSH, they remain polite and professional.

Because PPSH happens so frequently and can vary in its severity, participants had a complex and shifting relationship to the incidents they experienced. This complexity manifested in their responses to patrons, their emotions about incidents, and their own self-reflective reactions to PPSH after it occurred. Of note, participants often had to decide for themselves what were the workplace emotional labour ‘rules’ around sexual harassment; while PPSH often occurs at the library as an everyday part of patron interactions, there is little training and policy about it in library workplaces, it regularly goes under reported, and it has not received substantive attention in the LIS literature. Unlike other research contexts where emotional labour has been studied within library workplaces, participants were not often told by their employers’ directly to express specific forms of emotional labour in the face of workplace sexual harassment. Instead, participants’ post-incident reflections made visible how workplace expectations about being polite and professional influenced how they thought they should respond to PPSH, while they also managed their own individual fears, beliefs about sexual harassment, assessment of the situation, and personal preferences. Concepts such as emotional labour and emotive dissonance provide a vocabulary to “see” the complexity of these shifting responses. Indeed, drawing on the lens of emotional labour offers an alternative way to see “customer-library worker” interactions through the lens of the library worker rather than the patron.

Strategies that require emotional labour, especially indirect refusal strategies, are often encouraged and taught to library workers as customer service tools when they participate in library training programs targeted at providing “customer service” skill development and management. For example, redirection and de-escalation techniques are often taught as strategies to deal with difficult patrons. While certainly not denying the importance of these tools and their place in learning how to work well with library patrons, it’s also important to note that these strategies support the library ethos of the “customer is always right”, implying that library patrons need to be handled carefully and persuaded to do the right thing. The intention of redirection training, for example, is to maintain library safety for staff and all patrons, while using soft skills such as friendly persuasion to influence patrons to follow library rules. We need to consider however, the consequences for library workers of this orientation to “persuasion” and the ways that it may disempower them to stand up to instances of sexual harassment and abuse when being perpetuated against them.

Finally, it’s important to locate this research within the broader scope of research about emotional labour. Our findings resonate strongly with research that highlights the complex relationship between emotional labour and sexual harassment in service contexts, where emotional labour both encourages and is used as a defense against
sexual harassment (Good & Cooper, 2016; Kensbock et. al. 2015). Similarly, we found that patrons often misconstrued politeness as sexual interest. And conversely, library workers often tolerated or ignored sexual harassment out of fear for their safety. Our findings also support some of the LIS literature about emotional labour, particularly research that connects emotional labour practices to the feminization of librarianship, drawing on the concept of emotional labour to reveal how gendered practices of service provision and care work manifest in library work (Bright, 2018; Emmelhainz, Seale, & Pappas, 2017). However, we also wish to respond to some of the emotional labour research in LIS by noting that while there may well be opportunities to encourage positive emotional labour outcomes for library workers in some contexts (Schuler & Morgan, 2013), there should be no way forward that embraces any form of emotional labour as a strategy to address PPSH. PPSH is a form of gender-based violence that library patrons must understand is not acceptable. Effectives strategies designed to counter it must acknowledge the significant harm it creates for library workers when they endure it and when they respond to it in ways that do not centre their humanity, stories and experiences, personal feelings and emotions, and especially workplace rights. There is no silver lining associated with using emotional labour to manage harassing patrons. Our own program of research on the topic of PPSH continues to examine how library workplaces can more effectively respond to PPSH. Further research is urgently needed that considers instead how we can empower library workers and their workplaces “to find a way to say no.”

Stronger Than Yesterday: Investigating Peoples’ Experiences of View Strengthening on Social Media

ABSTRACT
Polarization of views (known as ideological polarization) is one of the greatest societal challenges of our time, potentially sewing distrust and hate among individuals and communities and threatening to undermine the fabric of democracy. Divisive issues such as abortion and gun control are ever-present and can drive issue polarization, and even affective polarization—a disdain for ‘the other side,’ which can further divide society. Social media has been flagged as a breeding ground for polarized views, with private groups and personalized algorithms facilitating self-creation of echo chambers that may lead to polarization. While there is prior research on the technological influences on view strengthening, scant Human-centered research exists and most of it has focused on view change in general, rather than view strengthening specifically. To investigate peoples’ experiences of view strengthening on social media, we interviewed 10 people who recently strengthened their views on important topics. While some took steps to avoid creating echo chambers (e.g., by seeking out opposing views), others intentionally created them to allow their views to strengthen without interference. These findings have important implications for designing social media platforms that support careful and conscious view strengthening while mitigating against the risk of information manipulation.

KEYWORDS
Human-Information Interaction, echo chambers, personalization, view strengthening, polarization

INTRODUCTION
Polarization is a complex phenomenon and can be political (divergence of political attitudes away from the center), ideological (what we think about an issue) or affective (how we feel about people on the other side of the debate) (Kubin and von Sikorski, 2021). Recent years have seen a sharp increase in polarization of all forms (Iyengar, et al., 2019), a change often been blamed on the internet or social media. While there is strong evidence that broadcast TV reduced polarization (Campante and Hojman, 2013) and that mobile internet has increased it (Melnikov, 2021), studies on social media have been mixed (Ferguson, 2021, Lee, et al., 2022). Polarization, particularly affective polarization, has deleterious effects on society: dehumanizing ‘the other side’ does not allow for the productive discussions necessary for a healthy democracy (Helberger, 2011) and can result in political divisions that outweigh considerations of honesty or decency. Understanding polarization is thus a highly socially important goal. While much work has pointed to the role of technology in polarization, we lack an understanding of the human perspective of how people move toward stronger, and thus potentially more polarized views.

While there is significant work understanding the causes and impacts of polarization, little work has focused on the role of human information interaction (HII) in this process. Research examining the role of HII in view change has noted that view strengthening is one possible outcome (Buchanan, et al., 2022, McKay, et al., 2022), but has not focused on view strengthening (and thus possible polarization) specifically. Understanding the human experience of digital information in view strengthening is key to understanding how we might design information and interfaces to reduce or mitigate polarization, and it is this issue this paper examines. We report on semi-structured interviews with 10 participants who had recently experienced a strengthening of their views on an issue of importance to them, to examine the under-explored question ‘what is the nature of HII-facilitated view change?’ Participants described a variety of factors as contributing to their view strengthening, including emotionally captivating images or video, deliberate avoidance of disagreeable information, and algorithmic support for highly personalized feeds.

The rest of this paper is structured as follows: first, we examine the literature on polarization, focusing on the role of social media to frame our research question. Next, we describe our data collection and analysis method, including ethical considerations. We then present our findings, before discussing them in the context of prior work and using them to propose design recommendations. Finally, we present conclusions and suggest avenues for future research.

BACKGROUND
Concerns about increased polarization characterize our era. Brexit (Hobolt, et al., 2021); the Trump presidency (Iyengar, et al., 2019) and, more recently, the COVID pandemic (Stoetzer, et al., 2023) have seen deepening differences in ideological position. These divisions in turn that make it hard to have the productive conversations and find the necessary consensus to live in a functioning society (Helberger, 2011). More worrisome than the ideological split, though, is an increase in affective polarization, where it is not just the views held by ‘the other
side’ that are held in disdain, but the people who hold them. This reflects the nature of polarization, where people ‘deny the existence of degrees’ by (over)simplifying an issue to ‘true’ or ‘false’ (Badia, 2019, p.309). In the case of affective polarization, people consider those who do not share their black-and-white views as objectionable. This can create a sense of group identity that influences their willingness to accept information (Haider & Sundin, 2022) and can push individuals to more extreme views in the direction of their prior-held views, known as ‘group polarization’ (Sunstein, 2019).

The internet in general and social media specifically have been blamed for a rise in affective polarization (Ferguson, 2021, Iyengar, et al., 2019, Kubin and von Sikorski, 2021, Lee, et al., 2022, Munn, 2020, Rathje, et al., 2021). There is some evidence to support this: while broadcast television increased consensus and reduced polarization (Campante and Hojman, 2013), the introduction of mobile internet, allowing people to readily access a huge array of information (and misinformation) from their pocket, appears to have increased it (Melnikov, 2021). While it is easy to blame social media, with its highly personalized feeds, results of studies of social media use are mixed: some show an increase in polarization (Lee, et al., 2022), others show no change (Ferguson, 2021). No study has shown a decrease though.

So why might the internet in general and social media specifically promote polarization? One leading theory is the notion of ‘selective exposure’ (Kelly, 2009, Valentino, et al., 2009). The internet allows people to find others with interests similar to their own and engage more strongly with information they agree with (Bruns, 2019), even if that information is highly biased (Bakir and McStay, 2018). One common way of discussing this phenomenon is through the notion of an echo chamber (Sunstein, 2018): people prefer to surround themselves with people and ideas they agree with and algorithms support this approach, either because they are designed to (Pariser, 2011), or because people ‘curate’ or train them to provide the kind of information they prefer to see and keep other information out (Lee, et al., 2022).

This theory is appealing and easy to support, with studies showing little engagement with news from a different political polarity (Bakshy, et al., 2015, Flaxman, et al., 2016, Weeks, et al., 2016) and people avoiding conversations on social media with those with whom they disagree (Sargeant and Tagg, 2019). Conversely, though, it has been argued and demonstrated that people are unable to entirely insulate themselves from disagreeable views (Bruns, 2019, McKay, et al., 2022), and that in fact, regular exposure to views from the other side actually increases polarization (Bail, et al., 2018). Furthermore, views from the other side are more likely to be shared on social media and generate stronger emotional reactions than the views people agree with (Rathje, et al., 2021). One attempt to explain increased polarization in this context is the notion of the ‘backfire effect’, where exposure to views other than one’s own serves specifically to entrench views (Nyhan and Reifler, 2010). Another hypothesis is the notion of ‘sorting’: that while traditionally we have shared some views and disagreed on others with most people, digital media is influencing us to have fewer cross-cutting opinions, creating ideological in-groups and out groups. The mechanism by which this is thought to occur is that, in being exposed to several views other than our own online, we become irritated, and influenced to shift our weakly-held views to align more closely with people with whom we share strongly held views (Tömpberg, 2022). This theory fits with recent studies of debunking misinformation, which have shown debunking is most effective when it comes from those like us (Lewandowsky, et al., 2012). At this stage, though, sorting theory is conceptual; it has not been empirically validated.

Understanding how polarization (particularly affective polarization) occurs is a key challenge of our time, as we try to decrease social division and preserve democratic values. It is perhaps surprising, then, that little work has examined the human experience of becoming polarized. Which do people experience as more important in influencing their own? Shared views or opposing views? What kind of information plays a role in this process? Is social media an important factor? In this paper, we begin to address these questions from the perspective of understanding the role of social media on view strengthening, recognizing that, at an individual level, polarization is a specific form of view change: strengthening one’s views.

While there is an extensive literature on view change in psychology (Petty, et al., 2003, Wood, 2000), it has not examined strengthening views specifically, nor has it focused on the information that contributes to view change. A recent study on the human experience of information in view change observed some instances of view strengthening, where people thought their views had become stronger over time, but also did not investigate view strengthening specifically. That study demonstrated that view change is often seeded by a passive information encounter on social media, and that many of these encounters are with emotionally impactful images or video (Mckay, et al., 2020). After this initial encounter, follow-up information seeking supports the view change. We cannot say, though, whether these patterns are true of view strengthening. This paper begins to address this gap.

**METHOD**

To understand peoples’ experiences of view strengthening on social media, we conducted semi-structured interviews with 10 social media users, lasting 45-60 minutes. We now explain and justify our participant recruitment, interview and data analysis approach and associated limitations and ethical considerations.

Ten participants were recruited through the primary researcher’s networks, social media and snowball sampling; we looked specifically for people who had experienced view strengthening as a result of information interaction on social media. This sample size is not unusual for studies of human information interaction, especially where the experience under investigation may be hard to pinpoint, see for example (Makri, et al., 2014, Marshall and Bly, 2005). Of our participants, six identified as women, three as men, and one as non-binary. All participants lived in...
Europe, the UK or the US; all were 18-35. Prior to participating in the study, participants completed a screening
survey where they briefly overviewed the view that had been strengthened. This was to avoid discussing views that
either the participants or the researcher would find upsetting to discuss. No participants were excluded from the
study on this basis.

We conducted semi-structured interviews by Zoom with all participants. Online interviews allowed for
geofraphically diverse participation and allowed participants to screenshare information that supported their view
strengthening. In the interviews, we asked participants about information-related aspects of their view strengthening,
including: what information they found on social media that had strengthened their views, what they did, thought,
and felt when they found the it, how the information strengthened their views, and the effect this view strengthening
had on their subsequent beliefs or behaviours. While these topics were covered with all interviewees, the interview
style was discursive and curiosity-driven, to elicit as much detail as possible from participants about their
experiences. To avoid shaming participants for their views, we took an empathy-first approach to interviewing,
much like that described in (McKay et al. 2020), which focuses on view change generally rather than view
strengthening specifically.

Interviews were transcribed automatically into Dovetail, which was used to support an inductive, reflexive thematic
analysis (Clarke and Braun, 2021). Transcripts were supplemented by screenshots from the screen recordings; when
an interviewee referred to a specific social media post/image/video, we pasted a screenshot of it in the relevant
transcript section. This facilitated easier and more in-depth analysis and reporting. Initial codes were formed, then
iteratively refined and grouped into themes. For example, this segment from P1’s transcript was initially coded as
‘importance of other people’ and ‘importance of empathizing with others’ for strengthening views: “You see that
this TikTok resonated with other real people...that further supports that there are real people affected by
this...because this had one million likes at one point...” These codes were then organized into the overarching theme
of ‘Empathy is the main driver for view strengthening.’ Data collection and analysis was iterative; we analyzed each
interview before conducting the next to alert us to interesting emerging findings.

The study was approved by our university ethics committee. Given the sensitive nature of many of the views,
participants were reminded they could pause or stop the interview at any time; the interviewer retained the same
right. Participant debriefs were conducted immediately after each interview to ensure participants were not
discomfited by the experience. No participant expressed negative emotions during the debrief, and many explicitly
described having the opportunity to reflect on their experiences as positive. While our findings may be
misappropriated to manipulate people into strengthening their views these risks are already at play on social media
(e.g., the Facebook emotions study (Kramer, et al., 2014)), this research does not pose additional risks, and may
offer opportunities to mitigate them.

Our study has two main limitations. The first is lack of participant diversity: nearly all were the researchers’ social
contacts, and all were college educated and aged 20-35. While our findings may not be generalizable beyond this
group, previous research has demonstrated that education level and age do not increase the likelihood of being in an
echo chamber (Dubois & Blank, 2018). The second limitation is recall bias. This study relied heavily on participant
recall, which may be unreliable. To mitigate against this, we focused on specific, concrete examples, and told
participants it was fine if they couldn’t remember specific aspects of view strengthening.

FINDINGS
In this section we present our findings. We first explain how it takes only a single information encounter to incite
view strengthening, then address the role of algorithms in those encounters. Next, we examine the role of emotional
content, and discuss information verification practices in view strengthening, before moving on to the role of
previously known information. Finally, we discuss avoiding and engaging with opposing views, before
summarizing.

It Only Takes One Encounter: Passively Encountered Information Catalyzes View Strengthening
While previous studies of the role of HII in view change found a one-off information encounter is not enough to
change views outright (McKay et al., 2020), we found a single passive information encounter (Erdelez & Makri,
2020) was responsible for view strengthening in nearly every case. This is, perhaps, because view strengthening is
even more incremental than outright change. These information encounters were often on social media feeds, and
highlighting the importance of passive encounters on social media for strengthening views. As an example, P3
strengthened his view on the severity of climate change by passively encountering, on social media and elsewhere,
information about ‘Fridays for Future’ - a school-aged student strike where youth skipped Friday classes to advocate
for climate change action. Being exposed to this information from several channels contributed to P3’s greater
climate awareness and the strengthening of his view on the issue. P3 stated “it was everywhere. It was in the news, it
was in newspapers, social media, in conversations. That was definitely a driver to get deeper into the topic.” P3
explained “the strengthening probably wouldn't have taken place without the topic being discussed and without
having the awareness."

For P9, an infographic (Figure 1) encountered on TikTok sparked her awareness of food regulation differences by
country, leading her to be more conscious about the food she eats in the US. She stated “I actually never questioned
it before I saw the TikTok or the side-by-side comparisons. ” Had it not been for this single serendipitous information encounter, P9 may not have felt the shock that led her to educate herself more about food ingredients.

![Image of food ingredients comparison](image)

Figure 1: Infographic in a TikTok video illustrating a side-by-side comparison of ingredients comparable ‘Quaker’ oatmeal cereal in the US (left) and UK (right)

It is notable that almost all view strengthening was facilitated by information that was passively acquired, as passive acquisition requires relatively little effort as compared with active seeking. This can be considered both a blessing, as it allowed participants’ view strengthening journeys to progress naturally in response to incidental information exposure, and a curse, as once started, these journeys often continued despite the lack of intent to progress them.

**Who’s in Control? User vs. Algorithmic Agency in View Strengthening**

While most participants perceived they had full control over their view strengthening, the strong role personalized algorithms played in curating and promoting content in their social media feeds highlighted a blurred boundary between user and algorithmic agency in view strengthening. For example, after P9 encountered the TikTok video comparing food ingredients in the US and UK (Figure 1), she actively searched for information on what ingredients were used in the US but banned elsewhere, and how to avoid them. She found an abundance of information that compared food ingredients in similar products across different countries, leading her to believe that people were becoming more aware of this issue. However, she still questioned the algorithm’s role: “the algorithm has definitely picked it up on Instagram and TikTok...this infographic wasn’t the only one I’ve seen. I would say people are taking a stronger stance on it. But I could just be influenced by the fact my algorithm has picked it up.”

In contrast to P9’s experience was P5, who was attempting to transition from vegetarianism to veganism. He explicitly sought out and followed certain types of content to ‘create a bubble’ of information by following organizations such as Greenpeace, who posted information he related to veganism, such as climate change news. He argued that this could be a positive way of allowing his views on vegetarianism to strengthen: “I realized that, if you want to be vegetarian or vegan, you kind of have to create your own bubble and find your own websites, social media platforms, friends, and realms...which makes it, on one hand, easier for you to stay vegetarian or vegan and on the other hand it gets you more information. You then realize this is a good thing to do, because if you don’t, you are always confronted with the opinions of others that contradict yours.” (P5).

This highlights a blurred line between whether peoples’ views are strengthened autonomously, or due to algorithmic curation of their social feeds – where content is personalized partly based on previous information consumed. This blurred line may make it difficult for people to detect when their views are being unduly influenced by personalized content. Furthermore, it highlights the risk of passively encountered information reinforcing a particular viewpoint and potentially influencing peoples’ views as a result, such as by strengthening them.

**I Feel for you: Empathy is a Key Driver for View Strengthening**

Empathy with the personal experiences of others was a key driver for HII-facilitated view strengthening. These experiences were often reflected in comments made or videos posted on social media by people who want to share their them. While no participants discussed examples where their view strengthening process had been manipulated by misinformation evoking empathy, the persuasive power of empathy-evoking information was considerable, and this had a strong impact on view strengthening. Understanding the personal experiences of others was crucial for many view strengthening journeys. For example, P2 expressed how others’ personal stories made her feel stronger in her pro-choice view, to the point she would advocate for and discuss it (despite originally being neutral and avoiding discussion on the topic). She stated that articles featuring the personal abortion stories of women “would strengthen my view...for me, the personal stuff is really what makes me more active.” Similarly, P4 stressed that
“hearing from all the sex-trafficking survivors...that really strengthened my viewpoint...it's just so impactful.” As most informational catalysts for view strengthening were passively encountered (e.g., on personalized social media feeds) this highlights a compound risk of manipulation through empathy-evoking content. Participants did, however, demonstrate awareness of some risks of information manipulation on social media through empathy evocation, such as the risk of impersonation. For example, when viewing personal experience posts on social media, P8 said she would routinely view the profiles of those sharing personal experience posts to ensure they were really the person they claimed to be--and sometimes she found that they were not: “I would always check who the posts are from...I would try to make sure they are not from some random individual...I ran into a bit of a problem there.”

Even the perception that others empathized with a post could strengthen viewpoints. For example, P1 based her perception of others’ viewpoints on the amount of likes and comments on a particular TikTok video (Figure 2) which humanized women who have abortions. She stated “you see that this TikTok resonated with other real people...that further supports that there are real people affected by this...because this had one million likes at one point, one million people who supported it. I know that the numbers don’t always matter, but at the same time...in the comments you're going to see people who probably relate to it.” While, on one hand, this illustrates that engagement measures such as likes and comments can be useful in supporting view strengthening, on the other it highlights the risk of placing disproportionate weight on the views of a subset of the population, which may make a view appear to have greater support than it really does. This can potentially bias view strengthening.

Figure 2: TikTok video humanizing women who have abortions (left) and example comments on it (right)

Built on (Potentially) Shaky Ground: View Strengthening Based on Unverified Sources
None of the participants described examples of view strengthening that seemed to be based on demonstrably false, or misleading information. However, some did describe trusting information that displayed only surface-level credibility indicators (e.g., cited sources, trusted author, source or brand names) and, crucially, participants rarely verified this information (e.g., by looking up the cited sources, or the author/source/brand). This highlights a possible risk of people placing misplaced trust in information that looks credible on the surface, but is actually false or misleading, and strengthening their views based on this ‘bad information.’ For example, P6 considers herself pro-choice (supports the right to abortion). She passively encountered an infographic on Instagram shortly after the overturn of Roe v. Wade (a US Supreme Court case making the right to abortion law, which was overturned in June 2022). P6 felt comfortable trusting the infographic as it cited the source of its data. P6 stated “it has a source, NPR 2022, on the first slide. So, I know that it's factual. It basically debunks some commonly held misconceptions of abortions...but it also strengthened my view.” P6 demonstrated an awareness of the importance of not grounding her views in unreliable information, stating “I never want to be hypocritical or ignorant about my views. So, I did my best to search for pieces of information with sources.” However, notably, she did not actually visit the source to verify its credibility, or its contents, and the source itself was not clickable to facilitate this. Although NPR is generally considered trustworthy, content may creators to falsely cite a credible source to gain trust and people may therefore strengthen their views based on misinformation. On one hand, participants demonstrated an awareness of the importance of credibility on social media. On the other, they rarely verified information found on it, instead often taking trustworthiness at face value.

Shaped by What I’ve Seen Before: Interpreting Information in Light of Prior Information Consumed
In line with prior work, previous information participants had consumed shaped the way they interpreted future information (Badia, 2019, p.309) and this often encouraged them to continue strengthening their views in a direction they had already started to travel in (Sunstein, 2019). For example, P10 had already begun to question the common but incorrect view that PCOS (Polycystic Ovary Syndrome) only affects women’s reproductive systems, by actively seeking PCOS information. She later came across an infographic on PCOS (Figure 3), which claimed to compare the myths and facts about the condition. She stated she “liked it a lot because it did address what I thought I
knew...what I was told...that PCOS just affects your reproductive system.” This helped strengthen her pre-existing view that the symptoms of PCOS are not all ovary-specific. Notably, however, although P10 said she appreciated information that cited its sources, she discussed an example where she had trusted information that did not cite its sources but mirrored her existing knowledge and beliefs, without verifying it. This may reflect confirmation bias, as she may have allowed her previous knowledge to convince her that this information was factual. It also likely reflects selectively choosing what information should influence one’s viewpoint based on information previously consumed (see later discussion on selective exposure). On the one hand, selective choice in light of prior information allows for regular reflection on one’s views, which may prevent the risk of manipulation. On the other, it might lead to manipulation by reinforcing views grounded in false or misleading information. While we cannot assume P10 was manipulated through confirmation bias, this example highlights the risk of over-relying on existing beliefs when interpreting new information.

Interpreting new information in light of previous information did not always nudge views in an existing direction, according to a pre-established trajectory. Sometimes apparent contradictions or inconsistencies between the pre-existing view and new information spurred participants to question their beliefs and, on occasion, change their views and then embark on a new, gradual view strengthening journey. For example, P5 was very aware of, and felt guilty about, inconsistencies between his current view on veganism and a documentary he had watched—‘Seaspiracy,’ which spotlighted animal welfare issues in factory farms. He stated “the reasons for me being vegetarian always made me a bit ashamed because they’re the same reasons why you should be vegan. I’m trying to save animals and I’m trying to save the climate...I am still eating, for example, cheese or eggs...Most of these things still contribute to factory farming.” This resulted in him attempting to transition from a vegetarian to a vegan lifestyle (based on a strengthening of his views on the importance of minimizing consumption of factory-farmed products).

P2 also expressed discomfort with the way she finds news: “I’m never really happy how I gather information. ‘Cause my main source is Instagram and I just think it’s so bad, so I try to make it better.” Despite her discomfort, P2 continued to utilize Instagram, particularly linked articles posted on Instagram stories, including from news sources, as her main way of consuming abortion-related news. To alleviate this discomfort, she deliberately diversified the news media accounts she followed on Instagram, to expose herself to a wider range of sources and opinions.

P5 stated he deliberately watched difficult media to shape his views in response to it, thereby confronting his cognitive dissonance. Non-deliberate information consumption (e.g., passive, incidental encounters) also built on prior information engagement. For example, when P5 happened to watch a cooking show that (presumably accidentally) ran a “cute” lamb video during an ad break and a demo of how to cook a lamb steak shortly after it, he felt shocked and disgusted at the juxtaposition. However, he recognized that he likely would not have had the same reaction years ago, when he was not yet vegetarian. This demonstrates that P5’s views, and associated view strengthening, were shaped by his prior information consumption. On one hand, this has the potential to guide people along a journey of gradual opinion discovery, perhaps strengthening their views along the way. On the other, if the prior information they build on is incorrect or unreliable, they may end up led the garden path rather than guided.

Choosing not to Hear: Selective information Avoidance Influencing View Strengthening

Some participants practiced topic-based selective information avoidance, where they avoided engaging with information about issues that had become emotionally distressing for them, such as animal welfare, abortion or gun control. Certain participants, such as P2, selectively avoided information to inhibit view strengthening: they did not wish to become further polarized. P2 selectively avoided all abortion-related information due to her overwhelm from the abundance of abortion-related information she encountered, particularly in her social media feeds. She was
conscious that, given the emotive impact this issue had on her, any information about Roe v. Wade, regardless of stance, was going to anger her and strengthen her view: “It was just basically everything I heard about it. It didn’t matter what medium, it didn’t matter what opinion, which side of the story. I just got really angry, and it strengthened my opinion.” P2 therefore temporarily selectively avoided all abortion-related information to try to prevent the emotional impact this issue was having on her from strengthening her pre-existing view further.

In contrast, some participants wanted to continue strengthening their view, and made a deliberate decision to selectively avoid opposing views to do so. In stark contrast to P2, P1 avoided information that opposed abortion, expressing her fatigue with hearing views from the ‘other side.’ She therefore only intentionally consumed pro-choice information that she agreed with. This allowed her to continue strengthening her view without having to consider opposing viewpoints, besides when (unavoidably) exposed to information incidentally. P5’s attempt to curate his feed was also an attempt to avoid information he did not wish to engage with; he stated: ‘you then realize [curation] is a good thing to do, because if you don’t, you are always confronted with the opinions of others that contradict yours.

None of the participants who practiced selective avoidance was entirely successful in completely shutting out opposing view; all reported, for example, passive, incidental exposure to the opposing view through social media feeds. This supports the argument that it is impossible to entirely insulate oneself from information on a particular topic (Bruns, 2019, Fletcher and Nielsen, 2017) and therefore highlights that echo chambers are more permeable than they are traditionally considered to be.

**Other Views Welcome? Opposing Views Strengthened Pre-Existing Views**

While some participants selectively avoided opposing views, others sought them out. This was often because participants were aware of the concept of an echo chamber and did not wish to become trapped in one. Take P7, for example: “you surround yourself with groups you agree with and in doing that, you create an echo chamber for yourself. So, you're not getting conflicting views anymore. I can even see that with myself...you're only getting people that agree with you and then you start to resent the people that disagree with you. I'm aware that this is a thing, so I try not to let it happen to me too much.”

While we did not observe the ‘backfire effect’ described in (Nyhan and Reifler, 2010), engagement with opposing views did not necessarily result in questioning or reflection, even where participants claimed this was their motivation for seeking these opposing views out. We did, however, see some instances where engaging with opposing views increased disdain for ‘the other side’ - a symptom of affective polarization. For example, P1 posted on Reddit to gain clarity on certain pro-life arguments on abortion, even though she was pro-choice. She did this not to reconsider her pro-choice view, but to understand the opposing logic and how to counter it. This strengthened her pre-existing view: “I posted because I couldn't really wrap my head around some of the arguments that I wanted to discuss...It was valuable too, because some doctors would respond... and I was like, ‘you know, the DNA argument, do we consider something that has DNA as existing?’ They responded ‘well, if I had a big vat of DNA in a soup, would you consider it murder to kill that?’” This can be considered an example of finding out enough about the opposing view to convince themselves their pre-existing view was correct. It does not demonstrate a ‘backfire effect,’ but a confirmation effect - it strengthened P1’s view by confirming rather than challenging it.

P7 expressed that opposing information, if rooted in fact, could encourage him to change his viewpoint. He stated “when I find new information on something that I believe and the new information disproves it, I tend to gravitate towards the newer information, because that's just how science works, right? Your viewpoint changes based on new information.” While he stated he trusted science and would alter his views in light of new facts, when he encountered opposing views, his view strengthening accelerated. When asked about the important factors in his view strengthening, he mentioned apathy amongst those who were against gun control in the US had played a key role.

For P2, reading the opinions of those against her own viewpoint directly led to strengthening her own view. “I'd read one article about people who are ‘Pro-Life’ and even that will strengthen me. I just see the bullshit they're talking about. It's basically just like, I cannot take you seriously.

Some participants tried to avoid entering echo chambers by staying aware of when they were about to enter one. This was to ‘keep in’ alternative views and avoid a scarcity of viewpoint diversity influencing the strengthening of their views (by leaving them unchallenged). For example, P7 was aware that self-creating an echo chamber would shut out opposing views and could result in affective polarization, so tried to avoid it by actively seeking out opposing viewpoints. He stated “you surround yourself with groups you agree with and in doing that, you create an echo chamber for yourself. So, you're not getting conflicting views anymore. I can even see that with myself...you're only getting people that agree with you and then you start to resent the people that disagree with you. I'm aware that this is a thing, so I try not to let it happen to me too much.”
Summary of Findings
Information from social media played a fundamental role in view strengthening. Usually, it was passively encountered rather than actively sought and often only a single piece of information was needed to drive view strengthening. Of particular concern is that, while some discussed curating algorithms, they may have less agency in influencing their personalized feeds than they think. Most informational catalysts were videos and this media type often grabbed peoples' emotions; empathy was the main driver for view strengthening. While several participants claimed to value source credibility, especially on social media, few invested efforts to verify content and platforms did not make sources easily scrutable. Peoples' views were shaped by information they had seen before, often encouraging them to continue on a pre-established view strengthening trajectory. Sometimes, however, contradictions or inconsistencies with prior information prompted them to question their existing views. Whether participants intentionally sought out opposing views or selectively avoided them, view strengthening still occurred as a result. Furthermore, they did not always selectively avoid opposing information to allow their views to strengthen; sometimes they did so to pause strengthening (e.g., when faced with too much emotionally distressing information). We now discuss the implications of these findings and propose design suggestions aimed at reducing the effect of polarization through social media.

DISCUSSION
In this section, we discuss our findings in the context of previous work. We first provide an overview of the polarity of information that strengthened views relative to participants own views. Next, we discuss the key role of information encountering, and the importance of algorithms, before broadening to discuss the role of social media in polarization. Finally, we examine the role of algorithms and the agency people may (or may not) have to influence what information they are exposed to. Based on this discussion, we then make design recommendations for social media platforms.

Selective Exposure, or Opposing Views? It's Complicated
Our findings paint a complex picture of the role of information on social media in view strengthening. We noted some behaviors that align with notions of selective exposure: our participants stated they wished to avoid information they disagreed with, and some of them even used the language of echo chambers and filter bubbles; for example, P5 described deliberately ‘creating a bubble’ and P7 wanted to avoid ‘creating an echo chamber’. This selective exposure was used by some participants to strengthen their views, as in the case of P5 and P2, but not by all; P1 wanted to avoid strengthening her views and practiced deliberate selective exposure to achieve this aim. Moreover, while participants described sometimes wanting to entirely avoid information reflecting opposing views, none of them were completely successful in this attempt, supporting previous work (Dubois and Blank, 2018).

Alongside those who inadvertently engaged with opposing views, and in contrast to selective exposure theory, we also found some participants consciously chose to engage with opposing views. They did this to avoid falling into an echo chamber, in pursuit of factuality, and to deliberately keep an open mind. While these are laudable aims, our study found consuming information reflecting opposing views clearly strengthened pre-existing views. It might be tempting to dismiss this as the backfire effect, particularly when P2 describes the views of others as ‘bullshit’. However, most of our participants described carefully considered approaches that seem far removed from accidental backfire.

In contrast to those who wanted to open their minds, some people engaged with information they disagreed with to strengthen their own views, by formulating counterarguments. This replicates findings of previous studies (McKay, et al., 2022, Weeks, et al., 2016), and supports the presence of confirmation bias. Our finding that peoples’ views were strengthened when they encountered information that echoed information they had previously consumed also supports the presence of confirmation bias.

Overall, participants engaged with and deliberately avoided information that both reflected and opposed their pre-existing views, for various reasons. Some wanted to strengthen their views. Others wanted to involve their views intensifying, which they saw as negative. Regardless of participants’ intentions, though, both selective exposure and exposure to opposing views did result in view strengthening. This paints a complex picture of view strengthening that demonstrates a variety of information contexts in which it can occur and highlights the complexity of issue and affective polarization, and may support the partisan sorting hypothesis, though more work is needed (Törnberg, 2022).

Importance of Information Encountering
A consistent feature of view strengthening was the pivotal role of information encountering (Erdelez & Makri, 2020). Rather than deliberately and actively engaging only with information they agreed with (and potentially becoming more polarized as a result), all participants strengthened their views as a result of passively encountering information in their feeds. This aligns with a previous study’s findings on HII-facilitated view change, which demonstrated it is often seeded by a serendipitous encounter (McKay et al., 2020). In contrast to that previous study,
though, and of deep concern in an era of widespread polarization is our finding that a single information encounter was responsible for view strengthening in nearly every case. In the previous study, multiple encounters played a role. Another difference between the view strengthening in our study, and the view change in that previous study is the limited verification our participants undertook. This contrasts sharply with the extensive follow-up information-seeking conducted in that study and may be explained by view change being ‘higher stakes’ than the incremental strengthening of a pre-existing view and therefore being perceived to require more supporting information.

**Role of Emotion**

Another common pattern of HII-facilitated view strengthening was the considerable emotional impact information encountered had on participants; all the view strengthening examples in our study reflected strong empathy. This strong emotional impact aligns with previous studies of view change generally (Petty, et al., 2003, Wood, 2000), which often have an affective component, and with studies of HII-facilitated view change specifically, which is often a result of an encounter with images or video that have a strong emotional impact (McKay et al., 2020).

Prior work on polarization also highlights emotion as playing an important role (Iyengar, et al., 2019, Lee, et al., 2022), and studies of how best to debunk misinformation show that appealing to emotion alongside fact can be helpful. Interestingly, negative emotion is also one of the drivers of sharing content on social media (Rathje, et al., 2021) (particularly negative emotion toward those who do not share one’s views) and that videos juxtaposing one’s views with those from another video are a particularly common and effective form of partisan communication on short video social media platforms, such as TikTok (Serrano, et al., 2020). Recent studies of news have shown an increasing preference for emotional content over fact based content in news, too, increasing the use of social media as a news source (Vosoughi, et al., 2018). It is clear that emotion is important, but the nature of its impacts present an interesting challenge: we now know that serendipitous encounters with information that provokes a strong or empathetic emotional reaction might change someone’s view or strengthen it. Understanding how we might predict the influence of a particular piece of information on someone’s view remains a key challenge for future work.

**Role of Algorithms**

Knowing that strong emotional resonance drives engagement on social media leads to a discussion of the respective roles of people and algorithms. We know that engagement drives social media algorithms (e.g. (Munn, 2020; Boeker and Urman, 2022). Indeed, Facebook has been accused of making algorithmic design decisions that exploit emotions such as anger and fear to drive further engagement, creating hate as a byproduct (Munn, 2020). Our study replicates previous findings that exposure to opposing views facilitated view strengthening (Bail, et al., 2018, Lee, et al., 2022), confirming that social media may be a driver of polarization, albeit indirectly and not in the way previously thought. Another way social media algorithms may drive emotion is by presenting increasingly extreme content, as occur when going down YouTube recommendation ‘rabbit holes’ (Ledwich and Zaitsev, 2020). More polarized information is likely to increase the strength of emotional responses, whether positive or negative, increasing engagement and affecting polarization in complex ways.

So how did participants describe the relationship between themselves and their social media algorithms? Some described deliberately curating their feeds to strengthen their views on certain topics, such as P5 who ‘created a bubble’ to support his transition to veganism. In contrast, others described their algorithms making decisions for them, such as to present similar information to that they had already consumed. While generally our participants expressed a high level of agency, it is unclear from our findings how much agency they actually had to manage their feeds. A recent study of interactions between people and when curating personalized TikTok feeds demonstrated that people found the algorithm surprisingly effective in selecting information to show them (Lee, et al., 2022). An examination of TikTok usage, though, shows that while there is some attempt to curate algorithms (as seen in our study and other work on view change), most of the control of the feed is ceded to the algorithm (Kang and Lou, 2022). While our participants attempted to exercise control and, for the most part thought they were in control, it is likely that, at least some of the time, they were overestimating their own autonomy.

**Does Social Media Polarize?**

Our participants described passive encounters with information that has a strong emotional impact as being a primary driver of view strengthening. While at first glance, this could happen with information in any situation, we see from the studies described above, that social media platforms specifically may be making view strengthening more likely. People are more likely to share social media posts showcasing the opposing views that sometimes drive polarization (Rathje, et al., 2021), meaning the feed of any given user is more likely to contain information of this kind than other kinds of information. The same study found that agreeable information was a high driver of likes; another signal of engagement. Engagement, in turn, drives the algorithms that construct feeds, potentially creating a vicious cycle. Passive consumption of information in feeds is key form of interaction with social media platforms (Kang and Lou, 2022, Lee, et al., 2022, McKay, et al., 2022), so how feeds are constructed is important.
Our participants demonstrated a desire to have input into the content of their feeds, both in terms of topic, and polarity of that content - a finding also echoed in other studies (Kang and Lou, 2022, Lee, et al., 2022, McKay, et al., 2022, Seargeant and Tagg, 2019). What we did not see, however, was an attempt to curate feeds based on the emotional strength of the content. It is thus up to social media designers to make this decision, and it seems likely that strongly emotional content is preferred, as it drives engagement.

Taking emotions and algorithms together, it seems possible that social media could drive polarization and we can see that, for our participants at least, interactions with social media did strengthen their views. However, these same features (the nature of the feed and highly emotional content) also drive view change (Mckay, et al., 2020). Therefore, the case for social media driving polarization only, as an inevitable outcome of view strengthening, is weak; it is likely that social media can polarize in certain, but not all situations. A future research challenge involves better understanding the situations in which polarization through engagement with social media can occur.

Design Recommendations
As we clearly found that information on social media strongly influenced view strengthening, the risk of polarization remains. Although how best to reduce the risk of polarization on social media is a question for further empirical research, we present three design recommendations that represent possible first steps. These recommendations focus on reducing the risk of affective polarization, on controversial issues.

Firstly, given the high emotional valence of information that prompts both view change and view strengthening, it is possible to adjust algorithms to promote more factual, and less emotional information on controversial topics. Previous studies have demonstrated that a feed of fact-checked information reduces polarization, while personal anecdotes increase it (Kubin and von Sikorski, 2021). As social media platforms can adjust what is presented based on its likely emotional impact (Kramer, et al., 2014), these approaches typically used to generate further engagement (Munn, 2020) can also be used to reduce the risk of polarization.

Secondly, social media platforms could encourage empathy-building, with people on all sides of controversial issues. While a social media user may not agree with another’s viewpoint or the ideology behind it, revealing commonalities with those with whom we disagree may reduce the sorting effect and thus the risks of dehumanizing the other side. Dehumanizing is a common feature of affective polarization (Hobolt, et al., 2021, Iyengar, et al., 2019, Lee, et al., 2022, Rathje, et al., 2021). Conversely, showing information presented by someone relatable is one of the more effective ways of combating misinformation (Lewandowsky, et al., 2012). Our participants highlighted the importance of empathy. Therefore, feeds could leverage this willingness to empathise to support social cohesion.

Finally, social media platforms could reflect the emotional valence of a feed and allow their users to curate their feeds for emotion, alongside topic and polarity, to reduce affective polarization. This would allow users to ‘turn down’ the emotion-provoking content in their feed when, for example, they notice their views are strengthening regardless of whether they consume agreeable or disagreeable information. Indeed, many of our participants said they did not wish to have their views strengthened and the only way to avoid this at present is by avoid certain topics entirely. Reducing emotionally impactful content could support people in staying informed, without necessarily becoming emotionally invested. How best to implement these recommendations remains an important question for future work.

CONCLUSION
Viewpoint strengthening is an important phenomenon that deserves to be acknowledged from the point of view of those experiencing it to better understand its causes and impacts. To understand the human experience of view strengthening, we conducted 10 semi-structured interviews with people who had recently strengthened their views based on information they found on social media. The findings provide new insights into the ways views are strengthened by digital information and emphasizes the crucial role of passively encountered information. The findings also highlight just how influential information that evokes empathy is; this type of information led to the strongest and most impactful view strengthening experiences.

While participants described both selectively avoiding and consciously engaging with information they disagreed with, the key role of passive encounters highlights the importance of algorithmic feeds on social media. Participants described both attempting to curate these feeds and being surprised by how the feeds responded to their information engagement. Both seeking out and deliberately avoiding information reflecting opposing views strengthened views though - so a diverse feed is no guarantee of reduced polarization.

We contribute novel insights into the role of social media in a specific type of view change (view strengthening). We now know the importance of emotional content and algorithms, and the complexity of engagement with opposing views. Based on these insights, our study offers several avenues for future work. These include investigating the role of sought information in view strengthening (social media is driven by passive engagement), the long-term effects of algorithm curation, and how best to tone down emotional content on feeds while still promoting engagement and support people in weakening their views, should they wish to do so. Understanding view strengthening from a Human-Information Interaction perspective can reveal new insights that, in the longer-term, may shed new light on how best to tackle the dangerous societal problems of polarization.
ACKNOWLEDGEMENTS
We would like to sincerely thank our participants and the ASIS&T reviewers for their valuable feedback.

The Hipátia Model: Paths toward the Brazilian Archival Digital Preservation Era

Braga, Tiago  IBICT, Brazil | tiagobraga@ibict.br
Alves, Larissa  IBICT, Brazil | larissaalves@ibict.br

ABSTRACT
This paper presents how Brazilian judiciary organizations are advancing towards a preserved digital environment, and how this process is improving the country’s legal system. First, it analyzed the legal norms published by some of the most relevant Brazilian institutions and how these norms fostered the major courts to immediately start projects related to digital preservation. Second, the major challenges faced by these organizations while fulfilling the legal requirements were listed, and a general strategy to attend to them was defined. Subsequently, a model was established to fulfill these requirements. The model was structured to consider the possibilities of future expansion. As the main result of this research, a model capable of setting archival digital preservation projects was designed for the first time, enabling their consequent application by judiciary institutions in Brazil.

INTRODUCTION
Digital preservation is one of the biggest challenges of this era, as the amount of data and information produced by society continues to increase daily. A few decades ago, discussions regarding digital preservation started being promoted by several researchers and institutions who were worried about how human beings would be able to access all the knowledge developed by us and the predecessors’ generations. Initiatives such as Mundaneum, promoted by Paul Otlet and Henry La Fontain (Pinheiro & Pereira, 2000), show the importance of keeping organized and accessible known information. With the advancement of digital information, new requirements have emerged, such as the maintenance of format compatibility, the need to assess risks related to digital infrastructure security, and the connection between distinct databases and repositories. All these aspects highlight the necessity of a well-designed and applied digital preservation plan.

Aiming to evolve the way digital information is organized and preserved, the European Bureau of Library, Information, and Documentation Associations (EBLIDA) has selected two main aspects to be considered in digital preservation strategies. The preservation of cultural heritage and scientific information was set as the top priority (EBLIDA, 2010) in the digital agenda for Europe. Proposals, such as those published by EBLIDA, were defined by other institutions around the world, and a diversity of standards and formats were made available. It is possible to highlight the Open Archival Information System Reference Model (OAIS) as an attempt to advance towards the organization of resident information technology (IT) infrastructure. The reference model was published by the International Organization for Standardization (ISO), and established general requirements that need to be covered by any digital information system (ISO, 2012) that aims to preserve digital information. The Library of Congress of the United States of America has also worked to improve the preservation of available resources. The institution developed the BagIt File Packaging Format (Kunze et al., 2018), which was used to organize the data and information into a hierarchical structure. Reference institutions from other countries have published guidelines to allow the implementation of IT systems that are capable of applying the requirements required by digital preservation standards. One of these institutions is the Brazilian National Council of Archives (CONARQ), which published a guide (CONARQ, 2015) to support the implementation of Trustworthy Archival Digital Repositories (TADR).

Although all these initiatives lead to better availability of digital preservation structures, the practical implementation of a TADR requires an in-depth understanding of organizational IT and documentation structures. The research conducted by the Brazilian Institute for Information in Science and Technology (IBICT) aimed to organize a series of methods and actions needed to understand institutional IT and documentation structures and provide the conditions for establishing a reliable TADR. This paper presents the Hipátia Model as a result of IBICT’s efforts to build a digital preservation informational structure that will allow Brazilian institutions to implement their own TADR based on a qualitative perspective and supported by an exploratory approach.

ARCHIVIST DIGITAL PRESERVATION
The methodological procedures defined to achieve the proposed objectives focused on the identification and analysis of the requirements of the TADR and building an applicable model. First, the most relevant norms were analyzed. The selection of these norms was based on the previous work of Pignataro et al. (2022). The requirements and structures published in these documents were considered during the subsequent phases. Second, some partner
organizations shared information about their IT and documental structures. This information was analyzed and used to propose practical actions based on an exploratory approach. Finally, while applying these actions, all steps were documented to allow future replication. The resulting document was organized as a model that received the name Hipátia.

**Norms**

In the last few decades, a series of specific norms have been published to foster and support the implementation of digital preservation projects. These documents cover aspects such as the characteristics of data storage and transfer, archival openness, audits, and certifications of trustworthy digital repositories, archival descriptions, and metadata.

Most of these norms aim to improve the way data and information are stored in digital systems and can be applied together, as they are complementary. Pignataro et al. (2022) published a list of these most known documents.

Table 1. List of most important publications related to digital preservation.

The fact that the ISO published a set of standards covering digital preservation between 2012 and 2014 has fostered the emergence of initiatives in Brazil. In 2015, CONARQ published guidelines for establishing the requirements related to TADR implementation.

Although the requirements and instructions are publicly available, the practical implementation of a TADR requires institutional action regarding the configuration of IT and documental structures. These actions are not simple and require effort and compromise from the IT team, documental team, and high administration board. It also requires that complementary aspects be considered. The next section discusses these aspects.

**Challenges implementing TADR**

During the research, IBICT shared information and supported some institutions, such as the Tribunal de Justiça do Distrito Federal e Territórios (TJDFT), the Arquivo Nacional (AN), and the Tribunal de Justiça de Minas Gerais (TJMG). These organizations provided valuable information and identified difficulties in implementing the TADR.

The team decided that the TADR should be strongly based on ISO standards, especially ISO 14721 and its Open Archival Information System (OAIS) Reference Model. This decision was supported by the fact that the Brazilian Archival Council chose this reference model for TDAR projects. The reference model presents preservation planning and its phases, namely ingestion, data management, archival storage, and access. It also includes three actors, namely producers, management, and consumers.

The phases need to use three specific packages to be successful: the submission information package (SIP), archival information package (AIP), and dissemination information package (DIP). Regarding the role of the actors, they could be executed by people of systems, that is, the case of the producer and customer, or simply by systems, that is the case of management. Management can also be considered as TADR itself.
With this reference model as the foundation of TADR, the identified challenges can be separated into three categories. IT and documental categories were previously identified by CONARQ (2015), but IBICT’s analyses identified that without organizational commitment, it would not be possible to move forward. Hence, these categories can be separated into IT, documental, and organizational categories.

**IT challenges**
The first IT challenge faced during this study was to identify software that could cover the phases proposed by the OAIS reference model. Because the company Artefactual has been working with archival systems for a few years, Archivematica and AtoM have been considered since the beginning. The AtoM fits almost all access requirements, whereas Archivematica covers aspects of the archival storage phase. The software to support the ingest phase is the hardest to find once it needs to be integrated into the producer system. During the research, it was determined that this phase must use software that can be configured to connect with more than one producer system. The research team then decided to build new software called BarraPres, which is composed of a solid structure that can receive different configurations through a data dictionary. The software was built in Python, and its configuration module allowed almost any producer to connect to the TADR once the correct data dictionary was prepared.

Once BarraPres was developed, the TADR had to install and configure three main software packages, BarraPres, Archivematica, and AtoM, and a few auxiliary software packages, such as MySQL, Python, and PHP. All these installations demanded a very specific configuration that allows information to be shared in a secure environment. The proposal identified as the most efficient was to create independent virtual local area networks (VLAN). This type of solution segments the organizational network and increases security once it is accessed through specific paths.

**Figure 1. OAIS reference model (ISO, 2012)**

**Figure 2. Software and VLAN configured during the implementation of a TADR**
Another IT challenge is related to the security. As the repository is intended to be the ultimate source of reliable information and document access, this question is one of the most important considerations. To increase the way TADR faces risks related to security issues, each application was installed in a different network segment; hence, there was no easy way to access data and information without an explicit connection. This process also contributed to the organization of the different modules and steps while implementing the TADR. An event-based application called Kafka was used to establish communication between the VLANs. This software allows message exchange between the networks and software.

Once the network hierarchy was defined, the team found that access control was necessary to guarantee correct communication during the TADR phases. Each software package was configured to have only essential access, thereby increasing the security and maintenance of the entire process. Consequently, the IT team was trained to understand and maintain the aftermath of the IT structure.

**Documental challenges**

One of the major challenges faced during the implementation of a TADR is related to its documental structure. To properly archive documents stored in an information system, it is important to understand their characteristics in detail. The format, available metadata, document extraction method, and related digital objects must be described. During the research, it was clear that, although the documental team knew a considerable number of characteristics related to the stored documents, some vital information was visible only to the IT team, and they were never accessed by archivists. To understand the available information and how it could be used, the team chose to deepen knowledge of the database. This allowed them to understand the hidden data and how they could be used to improve the storage process.

Once the data and metadata are listed, the documental team must build a data dictionary that can be used as a template to package the information extracted from the production system. The data dictionary must include the data identification, type, format, and location. In addition, it was used to assemble the BagIt file with several others.

![Figure 3. Data dictionary example](http://www.cnj.jus.br/tempos-guia-intercomunicacao-2.3/processo% all='ht)

Another challenge identified by the documental team is related to the manner in which the documents are disseminated during the last phase, as proposed by the OAIS reference model. The dissemination phase presupposes that the document and all data and metadata needed to bring the document context will be available. This means that the classification used to store the document in the producer system must ideally be used by the consumer. To enable this classification, the documental team proposed the use of two metadata standards: ISAD(G) and Dublin Core.

ISAD(G) is the general standard for archival description, and is used by Archivematica to provide a wide description of the stored document. Although ISAD(G) is a great standard, it is not recognized by AtoM to represent the document. Instead, AtoM uses Dublin Core, which is a metadata schema that provides broad coverage to represent almost any document type. Both metadata schemas are encapsulated by the submission information package and used at the right time by the TADR.

The documental team identified several other challenges. The definition of resources, such as the temporality table and business process management, is important for supporting digital preservation phases. Although they are not directly related to TADR implementation, they are crucial for the success of the process.
**Organizational challenges**

Organizational challenges focus on two main areas: financial sustainability and team integration. These areas are essential for ensuring long-term results and mapping risks associated with TADR implementation. In addition, the organizational team, composed of the institutional board, should define mechanisms to guarantee that the digital preservation project is endorsed by all teams.

There is no shortcut to financial sustainability. The funds must be allocated because once a digital preservation project is set, any lack of resources can be critical. Certainly, strategies can be proposed to soften the impact of such long-term commitments. In this project, the organizational team supported the use of open-source software. Thus, other institutions can contribute to the evolution of software. Additionally, it makes it easier to find partners and IT staff suppliers. However, the option for an open-source IT structure also implies that the institution will need to maintain a regular maintenance process as new vulnerabilities are quickly discovered and explored.

Although expense optimization is a very efficient strategy, it is not sufficient to guarantee a project’s financial sustainability. To do so, the organization also needs to allocate funds through long-term commitment. This is difficult because there is no certainty regarding the future scenarios. When discussing public organizations, there is a complication related to budget allocation, as there is no guarantee that it will be prioritized by the next government in the future. To address this challenge, the organizational team worked to establish partnerships with similar institutions. The fact that the Brazilian National Council of Justice published national norms covering digital preservation stimulated other institutions to join the initiative.

Once the financial challenge was solved, the organizational team had to deal with another important challenge related to the preservation culture. It is common for different teams to work independently; however, this approach does not work when discussing digital preservation. As the activities of the IT and documental teams depend on each other, they need to exchange information and procedures to optimize their actions. However, these teams were not used to working together. The activities executed by archivists tend to be associated with physical archives. On the other hand, the IT team are commonly linked to computational activities but not to the core understanding of the process. To face this challenge, the organizational team chose to programme an interchange agenda; hence, the teams had the opportunity to share their discoveries and support each other’s actions.

A vital step in achieving this cultural change was to integrate the teams. A documental team member was asked to join IT team meetings, and the opposite was true. This integration allowed the teams to understand what was happening in each area and to improve their own activities based on the results obtained by the other team.

These three challenge categories—IT, documental, and organizational—covered almost every difficulty encountered during the research. Integration of the strategies defined by each team is fundamental for developing an institutional strategy to implement TADR. This strategy was then schematized to allow for replication. This is how the Hipátia model emerged.

**THE HIPÁTIA MODEL**

The actions, methods, and procedures defined during the research were organized to allow replication. The schematization process was executed by IBICT’s team, which collaborated with teams from other institutions, such as TJDFT, AN, and TJMG. Hipátia was the chosen name for this model and refers to a woman who was considered the only female scientist in history for the fifteenth century (Cunha et al., 2015). Hypatia developed studies in mathematics, philosophy, physics, and astronomy in the Library of Alexandria and, after her murderer, most documents to which she was referred were destroyed; however, some of her studies and her role in coordinating the Library of Alexandria were rescued.

As previously discussed, the model is based on the OAIS reference model, but it is organized into five phases: data producer, extraction, packing, preservation, and dissemination. All phases need to be executed by integrated teams covering people from IT and documental areas. The model presupposes that all data, metadata, and documents will be shared through specific packages.

First, from the data producer phase to the extraction phase, all digital content is shared in an unstructured format, following the conditions provided in phase one. This digital content can be extracted using web services, the best choice, database direct access, and even physical file access, the last option to be considered. There is a module in BarraPres that is prepared to extract the information, and it can be configured for integration with any computational system. After this extraction, no access to any external system is required. All the other requirements can be internally covered by Hipátia.

The second phase sends information acquired from the data producer to the packing phase. During this process, a data dictionary is considered and used to organize and fulfill all requirements. The related metadata using both the ISAD(G) and Dublin Core schemas are aggregated and stored inside the initial transfer package. All documents...
were inserted into the package based on a hierarchical structure. This step is also covered by a BarraPres module, and the resulting package can be considered as the SIP presented by the OAIS reference model. This package will not be stored or shared; its use is temporary, and once it is analyzed in the following phase, it can be eliminated.

The next phase, preservation, was more intense. It is based on Archivematica software and is responsible for permanently storing digital content. After receiving the SIP, several microservices are executed to validate a wide number of characteristics. These microservices are divided into those focused on transfer and those focused on ingestion. As an example, transfer microservices can check the file structure, rename, generate a unique identifier, generate a METS document, scan for viruses, and so on. The ingest microservices can execute activities such as name verification, normalization, metadata processing and prepare the AIP and DIP packages.

All these microservices are executed internally in Archivematica; however, a comprehensive log is generated to allow the individual verification of all executed actions. An example of how microservice execution is checked by the software is shown below.

![Figure 4. Microservices executed by Archivematica](image)

If the preserved information can be shared, the DIP is created during the preservation phase and then sent to the dissemination phase. The dissemination phase is the last phase, and it focuses on making the preserved information available to customers. The Hipátia model proposes the utilization of AtoM to implement this phase, but other software, such as DSpace and Tainacan, can also be used. One important action executed during this phase is the recovery of the original document’s classification from the data producer phase. This is possible because all contextual information is stored in a database structure that is accessible from the dissemination software.

The figure below illustrates how these five phases are integrated and the main informational resources used by any one of them.
Given the execution of the five phases presented above, it is possible to analyze how Hipátia’s proposal can be used to establish a practical, feasible, and reproducible flow that considers the integration between concepts from the information and IT areas. Thus, in addition to enabling the implementation of TADR, the model reinforces the need to guarantee the chain of custody of digital archival documents, which is understood by Flores et al. (2016) as an unbroken custody line in the implementation of computerized systems for management, preservation, and access to digital objectives.

ADVANCES AND FUTURE PERSPECTIVES
The research is still in progress, and new features, concepts, and resources are constantly being added to the Hipátia model. In the near future, most justice institutions are expected to adopt it. Hipátia also fits with archival institutions, such as national and regional archives. Some partners have already identified the need to expand available modules. The digitalization module is one of the most required modules and probably will use artificial intelligence to recognize texts.

Other aspects to consider are related to integration with other initiatives and projects. As Hipátia is being adopted by several institutions, it is desirable that the model be coupled with management systems and initiatives. To achieve this objective, a strong institutional network must be developed around the Hipátia model.

Finally, Hipátia has been successfully adopted in Brazil, but it is expected to be adopted by institutions from other countries. Hence, it is important that documents, tutorials, codes, and interfaces are translated into languages such as Spanish, English, and French.

CONCLUSION
Ensuring that the content and context of the digital object remain accessible and authentic over time is characterized as the essence of digital preservation. Preserving archival documents and information from government institutions is a social concern related to the access and dissemination of national memory. The large volume of digital information produced and the need to ensure the security and authenticity of information make digital preservation the main priority when discussing the national informational agenda.

Considering the importance of the relationship between digital preservation and the construction and maintenance of a country's memory, this study aims to present some paths adopted by Brazilian organizations to structure a preserved digital environment based on a practical series of recommendations and actions. This methodology was organized and presented as the Hipátia model, which covers the implementation of the TADR.

To think about digital preservation involves considering aspects related to information, technology, and management. The development of this research on digital preservation, with an emphasis on the implementation of TADS, demanded collaborative and complementary work by a multidisciplinary team. The categorized challenges, IT, documental, and organizational, allowed us to understand how deeply the institutions needed to understand their own structures to succeed in implementing a TADR.

Finally, any initiative related to archival preservation will only be successful if the informational and computational aspects are considered by the administration. In addition, it is important that the teams have the autonomy to propose customizations, as the Hipátia model is a work in progress.
ACKNOWLEDGMENTS
The authors gratefully acknowledge the institutions that funded and supported the development of the Hipátia model. We thank the Brazilian Institute for Information in Science and Technology, Tribunal de Justiça do Distrito Federal e Territórios, Arquivo Nacional, and Tribunal de Justiça de Minas Gerais. Furthermore, we would like to thank the work and commitment of all the researchers who worked and contributed to structuring the Brazilian model for implementing the Trustworthy Archival Digital Repositories.

‘Routine Infrastructuring’: How Social Scientists Appropriate Resources to Deposit Qualitative Data to ICPSR and Implications for FAIR and CARE

Bratt, Sarah
University of Arizona, School of Information (iSchool), USA | sebratt@arizona.edu

ABSTRACT
This study develops a grounded theory of how social scientists facilitate qualitative data deposit and the impacts on making data FAIR and CARE. Drawing from 15 semi-structured interviews with U.S. academic social science faculty who deposited data to ICPSR, I take a resource-centric perspective to address the need for theorizing scientists’ use of resources to bridge the gap between underspecified, heterogeneous data practices and repository requirements. The two primary contributions of the study are: First, the identification of three types of resources that social science faculty use to structure data deposit routines, namely: 1) bottom-up, 2) top-down, and 3) borrowed resources. Second, I import a theory from crisis informatics, ‘routine infrastructuring,’ to explain how social scientists deposit data to ICPSR. Results reveal that the resources social scientists use function as ostensive routines. I argue routine infrastructuring is not only a way to enact routines but also creates routines. Findings also show ‘in-house’ resources have a mix of beneficial and negative impacts for data FAIR- and CARE-ness. This study advances the small but growing body of literature that examines routine dynamics in research groups from a resource-centric perspective to explain qualitative data deposit to research data repositories.

KEYWORDS
Research Data Management, Data Repositories, Qualitative Data, Routine Infrastructuring, ICPSR

INTRODUCTION
Since the inception of cyberinfrastructure (CI) and spurred by federal data sharing mandates (Diekema et al., 2014), organizations have provided resources to assist scientists with research data management (RDM) and data deposit. Academic libraries have offered support in the form of data management planning (DMP) workshops. Data repositories provide tutorials to demonstrate how to add metadata to the submitted dataset. However, while the ‘best practices’ for managing and depositing datasets to open research data repositories are relatively straightforward in some fields, other fields are grappling with challenges for creating general principles for data management and deposit, such as scientists in fields largely generating and (re)using qualitative data. Scientific norms are still emerging for data management and data deposit. For example, Leahey (2008) found that social scientists lack shared norms for editing data. Granted, many centralized resources do exist to guide the process of managing and depositing qualitative data. For instance, the Inter-university Consortium for Political and Social Research (ICPSR) offers a rich collection of tutorials, frequently asked questions (FAQs), a podcast, and synchronous consultations with ICPSR “support staff” (Swanberg, 2017). These resources are used by the community to navigate the deposit process. Nonetheless, qualitative data is heterogeneous, requiring scientists to improvise to manage and deposit data.

Yet, studies of data management in the social sciences reported a lack of convergence on norms for preparing qualitative data for deposit (Antes et al., 2018). The heterogeneity of qualitative data can pose challenges to developing generalizable best practices (Elman et al., 2010; Mozersky et al., 2021), a lack of convergence on norms for managing and depositing qualitative data that can lead scientists to improvise data management practices (Bratt, 2022, 2023). For example, scientists’ practices of anonymizing data to prepare interview transcripts for deposit can be ad hoc (Crowston & Qin, 2011). In other words, studies show qualitative data are heterogeneous (Antes et al., 2018; Mozersky et al., 2021), making it difficult to converge upon a universal set of guidelines or at least formally recognized best practices for requirements for deposit to ICPSR such as anonymization (Tsai et al., 2016), adding appropriate metadata (Antes et al., 2018), and defining the scope of the dataset (Elman et al., 2010). A critical gap remains between local data practices and repository requirements that social scientists must bridge to deposit data. As Gerson & Star (1986) emphasized, all standards are underspecified with respect to how to take specific action in a particular local context, which can impede “getting things done” including data deposit (Gerson & Star, 1986, p. 23). Bridges this gap can even determine whether scientific problems are “do-able” at all (Fujimura, 1987).

In recent years, the CARE and FAIR principles for data stewardship have taken a central role as important goals for research. FAIR requires that data is made Findable, Accessible, Interoperable, and Reproducible (Wilkinson et al., 2016). CARE requires data to have Collective benefit, to give individuals the Authority to Control, to invoke Responsibility, and to be sensitive to Ethics (Carroll et al., 2020). FAIR and CARE set forth ideals for data stewardship that are important. They allow us to accelerate social problems by enabling the “big data revolution” (Atkins, 2003), and leverage the explosion of digital traces and computational resources. However, under specification of how to manage and deposit qualitative data can undermine FAIR and CARE goals. For example, the...
Reproducibility dimension of FAIR is threatened by instances when ad hoc approaches to data management occur. That is, idiosyncratic documentation means that the processes that led to creating and processing the data are hard to reproduce. To take another example Interoperability can be undermined by the lack of convergence on metadata norms; Let’s say one researcher describes their dataset collected from people who are in prison as “felons” and another uses the term “incarcerated individuals” and still another uses “perpetrators.” While these terms can be reconciled to create a data collection for criminal justice scholars, without the work of synonymy and applying standard metadata, these disparate datasets would remain unconnected, thus lacking Interoperability. In addition to these technical issues, there remains a broader argument advanced by Sabina Leonelli (2018) that qualitative datasets may not need to have Reproducibility as a goal at all. For example, ethnographic approaches aim to achieve epistemic validity through other approaches than reproducibility (Leonelli, 2018). In addition to the negative impacts of the lack of agreed-upon norms on FAIR, the CARE principles can be undermined as well.

Amplifying these challenges, social scientists are increasingly facing pressure to share data in open research data repositories. The pressure applied by funders, federal mandates, and disciplinary norms (Kim & Stanton, 2016) to share data requires more resources to manage data and prepare data for deposit. On top of pressures to deposit data, the U.S. academic crediting culture remains publication-centric, disincentivizing data deposit (Allen et al., 2014). Given these challenges, social scientists face several barriers to managing and depositing data. Nonetheless, scientists deposit their data into data repositories; that is, submit datasets that are subsequently approved by ICPSR staff, and the datasets are published in the data archive. There are currently approximately 18,734 studies with associated datasets in ICPSR (ICPSR Data Archive, May 2023).

Scientists’ deposit of data to ICPSR given the underspecified disciplinary environment poses a dual puzzle for information scientists and organizations aiming to understand and support researchers in managing and depositing their data: First, how do social scientists deposit data in a research environment that disincentivizes deposit? Second, How do scientists decide what are the resources and best practices to draw from when norms for doing so have not yet converged? Although these questions are urgent, we lack an empirical understanding of the spectrum of practices and resources that enable data deposit. Moreover, we have not examined the implications of the lack of convergence on data preparation norms on scientists’ on achieving FAIR and CARE goals for research datasets.

To date, much of the work in research data management in library and information science (LIS) research has focused on the formal resources that researchers draw on to manage and deposit data. These include university resources such as academic library guidance for writing a data management plan and data repository tutorials for submitting datasets (e.g., the NIH’s YouTube series on using BankIt to submit to GenBank1). In contrast, scholars from the field of computer supported cooperative work (CSCW) have developed theoretical concepts that help us to understand how coordinating artifacts can facilitate data management. For example, boundary objects and their many variants, e.g., boundary negotiating artifacts (Lee, 2007), are useful for explaining how scientists coordinate materials and understandings across information worlds. While valuable for understanding the end of the research data lifecycle, the LIS studies tend to overlook how scientists bridge the gap between local practices and repository requirements to deposit datasets. CSCW theories like boundary objects and infrastructure perspectives foreground coordination concerns. By focusing on coordination, they explain how scientists bridge the gap between repository requirements and local practices. In this study, I argue if we continue to focus on institutional resources only, we run the risk of gaining only partial understanding of the artifacts, processes, and practices that culminate in data deposit. Failing to identify these resources in situ undermines long-term research data sustainability.

In this study, I address these gaps by developing a grounded theory of how scientists use resources from both outside their organization and within their research group. I contend there is a gap between the heterogeneous local practices and repository expectations. To examine this data-to-repository gap, this study takes a sequential exploratory case study approach (Creswell et al., 2007) guided by three sequential research questions:

RQ1: How do social scientists deposit data to research data repositories?

We observed that social scientists deposit data by drawing on resources that facilitated data management and preparation for deposit to ICPSR. For example, ICPSR requires data anonymization. There is not widespread convergence on how to anonymize specific datasets in many social sciences disciplines. Social scientists lacked guidance for precisely how to anonymize their specific dataset. As such, they improvised by searching for best practices and devices to anonymize data, and techniques that would make anonymization easier. These observations of the use of various materials and techniques led to the second research question, related to resources:

RQ2: What resources do social scientists draw from to facilitate data deposit practices?

---

1 For example, see “Webinar: A Submitter's Guide to GenBank, Part I” https://www.youtube.com/watch?v=OZxxsRm0pP4
Based on the resource-centric lens suggested by observations in the first phase, we focused on the tools and techniques social scientists used to assist them with data deposit. Social scientists described the materials and techniques that supported data deposit, some of which were used in well-established routines but some of which created structures where before there was little or none. We noticed that by creating these structures and routines had impacts on data FAIR-ness. The potential impacts of resource use, routine development, and FAIR data led to RQ3:

**RQ3:** How does the use of these resources (and practices) impact the FAIR-ness (Findable, Accessible, Interoperable, and Reproducible) of the deposited dataset?

To address the RQs, I draw from semi-structured interviews with U.S. academic social science faculty (n = 15) who deposit data to the Inter-University Consortium for Political and Social Research (ICPSR) repository. First, the study identifies three types of resources that social scientists use to manage data: 1) Top-down 2) bottom-up and 3) borrowed. Second, the study deploys ‘routine infrastructuring’ to conceptualize the resources and improvisational practices social sciences develop, appropriate, and adapt to manage and deposit data.

**BACKGROUND**

Researchers in computer supported cooperative work (CSCW) and science and technology studies (STS) have theorized how scientists deal with uncertainty, especially with respect to trying to meet the requirements of a data repository. The literature in infrastructure and boundary objects in the context of scientific data management can offer a foundation for the present study given its focus on how social scientists deposit to ICPSR and how the resources they use help or hinder making datasets FAIR and CARE. In the following sections, I review relevant literature in infrastructure studies and define concepts related to ‘routine infrastructuring,’ a concept developed in crisis informatics that deploys a resource-based perspective to investigate the research questions.

**Routine Dynamics in Everyday Research Data Practices**

People engage in routine practices in their daily lives – routines like making breakfast, going to work or the gym, and watching a movie involve routine practices to carry them out. Organizational scholars have conceptualized routines as identifiable patterns of action which multiple actors engage in within a specific context (Feldman, 2000; Semaan, 2019). Martha Feldman (2000) overturned the traditional notion that routines are fixed and resistant to change, showing empirically that people exercise agency to modify existing routines and develop new ones. This generative view of routines – known as routine dynamics – shows that routines have two interacting parts: the ostensive part and performative part (Feldman & Pentland, 2003; Pentland et al., 2012).

The ostensive part refers to the abstract patterns that people use to guide, account for, and refer to during specific performances of a routine, often codified in documents. The performative part refers to the actual actions people take to carry out the generalized routine. As Feldman & Pentland (2003, p. 101) define them, the ostensive part is an “abstract, generalized idea of the routine,” whereas the performative part consists of the “specific actions, [done] by specific people, in specific places and times.” For example, to make breakfast, the ostensive part is the conceptual steps such as ‘scramble some eggs,’ and might be codified, in part, in a recipe. The performative part is when you carry out the activities in context, with a specific carton of eggs in your kitchen. As such, a routine can be performed differently, depending on the context, e.g., using a whisk rather than a fork to scramble eggs.

In scientific practice, researchers carry out their work by engaging in routines to handle research data. The performance of data management steps is guided by ostensive disciplinary rules and norms for how to clean, store, and analyze data. Such rules and norms for data routines can often be codified in ostensive artifacts, e.g., lab handbooks, to make sure the data is handled in a relatively consistent manner. Data management routines vary between disciplines and represent shared challenges. ‘Big science’ disciplines like astronomy and genomics may appear to have tightly linked ostensive and performative routines. However, many early science studies have documented that even big science projects with mature cyberinfrastructure face challenges in managing data (Borgman, 2015), such as managing the interoperability of diverse LSST data in Astrophysics (Jenness et al., 2016), challenges with version control in Gravitational Waves at LIGO (Collins, 2003), and variations how and by whom data management tasks are performed (Scroggins & Pasquetto, 2020). In other words, even if there are computational scripts that tell computers how to handle the data (ostensive routines) they are not always specific enough to guarantee an exact execution of the process (performative routines). The social sciences may represent even greater challenges, given the relatively increased heterogeneity of data and ambiguous ostensive routines (or none at all) specifying the data management actions to take (Borgman et al., 2021; Mozersky et al., 2021).

**Infrastructures as Resources Supporting the Enactment of Routines**

To carry out routines, one entity people rely on is infrastructure. Bridges, highways, the power grid – these are what we traditionally think of as infrastructure: the underlying foundations, or supporting frameworks, of large-scale systems. Society relies on infrastructures as resources which enable us to carry out routine activities. Scientists rely
on computing infrastructures as resources to routinely do research, e.g., conduct experiments. Systems, like freeways, support routine travel to and from school.

While infrastructure is often thought of as physical (e.g., bridges) and technical (e.g., wireless networks), Star & Ruhleder (1994) showed how infrastructure is sociotechnical. That is, social practices animate the physical, technical, and information infrastructures, and that the physical and technical infrastructures are inextricably embedded with human relationships and organizations. According to Star "[a]n infrastructure occurs when the tension between local and global is resolved" (p. 114), where technologies provide affordances to users to serve their local needs. Furthering this work, human infrastructure is a key aspect of sociotechnical infrastructures. Lee et al. (2006) defined it as "the arrangements of organizations and actors that must be brought into alignment in order for work to be accomplished." Thus, the physical, technical, and information infrastructures depend critically on human infrastructure to effectively function, and, in turn, human infrastructure relies on infrastructure to support routines.

Prior research has shown that boundary objects are important for coordinating the work of disparate actors (Bowker et al., 2016; Burnett et al., 2014; Lee, 2007; Levina & Vaast, 2005; Star, 1989). Star (1989) and Star & Griesemer (1989) identified types of artifacts as boundary objects, data repositories. Lee (2007) nuanced the discussion of boundary objects, as material artifacts that coordinate routines across disparate "information environments," arguing that the term is not monolithic. Lee (2007) adds nuance in a research study of designers “using artifacts and surrounding practices to iteratively coordinate perspectives and to bring disparate communities of practice into alignment, often temporarily, to solve specific design problems that are part of a larger design project” [CITE]. Artifacts can change purpose, given their context of use. Lee (2007) identified sub-types of boundary negotiating artifacts, including "structuring" and "borrowed" artifacts. Structuring artifacts are coordinative schemas, objects, and/or materials provide direction by framing an ambiguous or underspecified step in the work process (ibid). Borrowed artifacts are defined as artifacts “taken from its creator in one community of practice and used in unanticipated ways by those in another community of practice” (Lee, 2007). In Lee’s study, the museum exhibit designers borrowed artifacts from communities of practice who were “in close proximity” to the designers. Like scientists facing uncertainty on best practices of managing data, the designers resolved uncertainty by appropriating from outside sources to address goals and problems as they arose.

‘Routine Infrastructuring’ in Social Science Data Practices

People use improvisational, creative, and adaptive processes to manage unexpected challenges and to bridge gaps in infrastructures when formal support is absent, ambiguous, or insufficient. To carry out these adaptive processes, they need resources, so they turn to those embedded in the ready-at-hand infrastructures. Prior work by scholars in crisis informatics find that people often improvise equipment or tools to perform tasks (e.g., Bratt et al., 2017). For example, studies show how people use the ready-at-hand resources, though not explicitly intended for the task, to respond to the aftermath of natural disasters like hurricanes, where people have creatively used doors as stretchers when formal medical resources are lacking.

In a similar way, scientists draw from a variety of infrastructures – physical, technical, informational, and human infrastructure – in their everyday data practices to carry out data management and deposit routines. Institutions like repositories and universities provide institutional resources, designated specifically to support data management and deposit. However, these resources a) do not always fill all data management needs, and b) cannot specify all the steps that scientists must take to make data deposit work, no matter how detailed the directions are (Gerson & Star, 1986). Therefore, scientists are forced to draw from resources, from both inside and outside of their discipline, and do the work of knitting together institutional resources with local resources to bridge the lack of centralized, formal resources to overcome a problem or function effectively – known as an "infrastructural gap" (Vertesi, 2014).

In this study, I argue that to bridge the gap between local practices and repository requirements, social scientists engage in routine infrastructuring practices, that is, “the intentional production of infrastructure as a means of achieving a particular goal or the desire to solve a particular problem” (Semaan, 2019). Semaan (2019) develops the concept ‘routine infrastructuring’ in the context of disruption and resilience – how people manage their everyday lives using technologies to enact their routines. Using examples of prolonged disruption, such as war, personal crises, and LGBTQ+ transitions, routine infrastructuring is a concept developed in crisis informatics to describe how routines are performed when a disruption in workflow occurs to bridge infrastructural gaps. Routine infrastructuring depends on the informal and formal resources – materials, know-how, or practice that are ready-at-hand, familiar, or just to “make do” in specific situations – to make local adjustments and assemble an infrastructure supporting the routine.

While it may appear that research data management in academic research is a radically different context than crisis informatics (e.g., war, personal crises), the lack of resources scientists experience is a type of disruption – it disrupts the flow of work, data management routines, and effective function of their team – a ongoing disruption which scientists ameliorate and bind back together through infrastructuring to enact and create routines for data
management and deposit. Like first responders who used a door as a stretcher in the aftermath of a hurricane, social science researchers use resources from informal or external sources to manage lack of ready-at-hand, internal, and/or formal resources. For example, information science studies surveying faculty data management practices show that scientists use unconventional resources to manage data, such as sharing data not via an institutional repository but using email or social media (Akers & Doty, 2013; Bratt et al., 2017). Another example is the use of dental software to protect data privacy when there were no non-cloud-based systems available. In this study, I argue scientists are deploying creative, improvisational, and adaptive processes to manage and deposit data through ‘routine infrastructuring.’

**METHODOLOGY**

This study follows an exploratory sequential case study approach (Creswell et al., 2007). I employed semi-structured interviews to collect data, selected for its utility in investigating a specific issue to best understand the perceptions of researchers as they recalled data deposit processes (Creswell et al., 2007). A protocol was created with questions and prompts so the interviewer interacts face-to-face or through synchronous video conferencing in an alternating series of questions and responses. The exploratory sequential case study approach was used for its ability to build on previous findings from the study in a step by step process. The use of the case study approach was selected because it allows for a flexible research design to capture the recursive nature of “real life events” in context. An advantage of a sequential exploratory case study approach is that it can address complex factors that captures the richness of a phenomenon in its organizational and social milieu (Lalor et al., 2013), such as in the case of social scientists who face multiple motivations and pressures to deposit datasets to ICPSR. The exploratory case study approach is a method that is appropriate for “how” and “why” research questions (Creswell & Poth, 2016), as in this study of how scientists deposit their data, and how and why they make decisions as to the resources they use.

The criteria for recruitment for participation was research-active faculty at R1 U.S. academic institutions who submitted to the Inter-University Consortium for Political and Social Research (ICPSR) within the last 6 years (2017-2021), and the data submitted is qualitative (can be part mixed methods). As a research site, ICPSR is an excellent space to examine a context in which there are growing guidelines, policies, and norms for research data. A total of 15 participants were interviewed for the study (Table 1).

**Table 1. Study Participants**

Participants were recruited by email. The interviews were conducted via zoom video conference in September – November 2021. The average interview length was 75 minutes. Interviews are audio-recorded and securely stored before transcription into a document for analysis. For confidentiality, individuals were assigned a unique ID (P1-15) in chronological order of the date of the interview. Sensitive information was removed from the transcripts (e.g., names of persons mentioned, discipline and university-specific information that may disclose the person’s identity). The audio files of the interviews were transcribed using the semi-automated software Rev.com and a verification of
transcription accuracy was executed by listening to each interview while following along with the textual transcript and correcting any errors while anonymizing the data.

The data was analyzed using content analysis and the constant comparative method (Glaser, 1965). Given the exploratory nature of the study, the sample of fifteen individuals who submitted to ICPSR for interviews was justified by consulting qualitative analysis sampling guides. The intention was not to generalize results to a broader population (Bauer, 2000, p. 200) but rather as an approach to surface initial themes and patterns among research experiences. Content analysis proceeded by identifying themes and sub-themes, concepts, and patterns in the participant responses and analyzed in chronological order of interview. The codes were analyzed for relationships, and the concepts and topics were discussed, iteratively, with 3 rounds of axial coding (Elo & Kyngäs, 2008). An inductive approach informed the three rounds of analysis, drawing from grounded theory (Strauss & Corbin, 1994). Grounded theory is premised on iterative coding of emergent themes, topics, and concepts. A coding scheme was developed based on the themes that emerged in analysis. The study was approved by the university IRB. The manuscript was sent to participants for their feedback on the interpretation of their interview data.

**ROUTINE INFRASTRUCTURING RESOURCES SOCIAL SCIENTISTS USE TO MANAGE AND DEPOSIT DATA TO ICPSR**

In the following sections, I describe the resources scientists use in ‘routine infrastructuring’ to bridge infrastructural gaps. In the case of the Inter-University Consortium for Political and Social Research (ICPSR), studied here, social scientists drew on three types of resources: ‘Bottom-up,’ ‘top-down,’ and ‘borrowed’ resources.

**“Bottom-up” Resources: Defining Ostensive Routines for Data Management and Deposit**

*Bottom-up resources* refers to the support systems researchers draw from by creating their own documents, templates, and procedures to bridge the infrastructural gap in existing resources for research data. For example, in the absence of institutional resources, that is, a lack of precedent, guidelines, or standard operating procedures (SOPs) for faculty to follow, faculty developed in-house documents. Participants created several documents, codifying the ways that had worked in the past to manage data, and facilitate deposit, including lab handbooks, interview study checklists, data management PowerPoint presentation slides to orient newcomers (e.g., students), medical acronym “cheat sheets,” and “quizzes” to train qual interviewers. Table 2 offers examples from my analysis and describes the relationship between the type of resource, their function, the participants, and whether the resource was developed in-house or externally.

<table>

**Table 2. Resources Faculty Developed to Bridge an Infrastructural Gap**

These resources helped to align the requirements from the ICPSR data repository and local researchers’ data management needs by coordinating among the research group. Surprisingly, the faculty in this study reported few...
lab handbooks or lab notebooks, a standard and widely used procedure for provenance in many of the natural sciences (Kanza et al., 2017; Schraefel & Dix, 2009). But other “template”-type documents were frequently used. The documents served to help organize lab workflows and reduce the labor needed to teach newcomers data procedures. Streamlining function was evident in the case of P2, a pre-tenure epidemiology faculty who specialized in qualitative data collection:

“You have to give students a template for the interviews or they're not going to all have the same font size and same formatting and whatever else. And the IDs need to kind of be consistent. Or should be, right? It's better for people accessing it if it is consistent.” (P2, epidemiology faculty)

P2 created templates when there were no guidelines for orienting newcomers. The formatting and font templates were one piece of an elaborate ecology of training and procedural documents. These documents did not exist on their own but were imbricated into P2’s data collection processes, and were carefully designed and coupled with other practices to achieve the desired outcome – in her case, data quality and thoroughness. The use of templates helped to ensure consistency and reliability for working with the data. Similarly, P11, a pre-tenure professor in public health described how she created templates after learning lessons from previous studies:

“We definitely had some templates when I started [Project X] … We were using Excel for a lot of things…So we had some shared templates for calculating hospitalization rates and I was like we should be doing this in SAS. This kind of fell by the wayside…When we're just focusing on analysis for the [Project Y] study there's definitely lessons learned that we have from the [Project X] study like the missing data” (P11, public health faculty)

The templates P11 described became taken-for-granted and naturalized as part of the research group’s infrastructure. The templates help to guide routines, serving as ostensive elements in performing data management routines. While at the start of P11’s project, Excel and SAS were considering for us, indicating an ambiguity in routines given the shifting between different technologies and discussion of which was better. Over time, SAS stabilized as the standard practice for templates for data analysis to be used. These templates had important implications beyond controlling data workflows. Not only did the template serve in ensuring data was collected consistently, and controlled according to faculty specifications, but had other results, some unexpected, such as scaling up the number of manageable students in a lab. P5, a tenured faculty studying criminal justice, explained how scaling a project meant a more complex division of labor. As a result, P5 needed to create standardized protocols for data management, in the absence of institutional resources:

“We had to have a level of organization that we didn't have in the past. Originally when we wrote the proposal, we said that we were going to use paper and pencil to go into prisons and collect data. Paper and pencil interviews, you know, in retrospect that's just silly. It's just that's not the way you collect data. Or at least it's not an efficient way to collect data. We had to hire the right people, the right research assistants and so on. And then we had 70 different interviewers that we trained on this project to conduct these interviews, whether it was in person in the prisons… Or if it was over the phone, which is what we did with the re-entry interviews.” (P5, criminal justice faculty)

The increased training and “level of organization” P5 describes made it easier to take on a larger number of students. The faculty directing the project did not need to apply as much effort to train students in data handling.

“Top-Down” Resources: Appropriated Artifacts to Manage and Deposit Research Data

Top-down resources are the tools, artifacts, and procedures and other supportive infrastructure that researchers appropriated from existing formal sources. For example, organizational policies or legal dictates – rules intended for purposes other than data management – were appropriated to coordinate data management and deposit.

A major motivation for re-appropriating existing formal resources for data management and deposit was to collaborate. Making routines explicit through shared documents, common rules, and centralized resources which people were already familiar with smoothed out and helped to coordinate among research collaborators. For example, P11, a pre-tenure faculty in public health explains how she created a shared document infrastructure to manage the moving parts of data across the research team and over time:

“We have a running Google Doc that we're calling our methodology report that, when we just realized this isn't going to be a summer project, this is COVID, it is not ending, let's, like, formalize some of these things. And we just started adding lots of information in there about things like weighting [variables]… So we had people on the team who are postdocs and leaving and we were going to lose that knowledge. We're like ‘let's start documenting.’ We were like ‘write that down because we're going to have to train somebody new on it and we don't know what you're doing’.” (P11, public health)
Some implications of the documents and standardized and centralized resources were making it easier to communicate with a distributed team, where the division of labor was modular. Common documents facilitated collaboration. Another example is faculty appropriated formal agreements and shared documents to organize data among a distributed research group, such as a Data Use Agreement, or a Memorandum of Understanding (MOU). Such agreements were often used to coordinate between centralized resources, such as core facilities, or have legal documents that describe the terms of use, e.g.: “We shared the data after the two universities signed the contract agreement, the data transfer agreement.” (P8, social epidemiology).

Because routine infrastructuring involves the work of re-aligning the goals of various stakeholders, which occurs where there are situations of uncertainty, the documents established certainty and understanding among stakeholders in advance. These clear rules and agreements helped to settle ambiguity to enact data management routines. For example, in the case of P3, a tenured epidemiology faculty, using a core facility or a recharge center, multiple participants have reported some of the documents they use:

“The ordering system helps you pinpoint the structure you need in your files and then [the manager] speaks to the programmer in language, the programmer will understand to set up the file structure and so it's kind of a process where I create specifications using words, like, I'll write a paragraph or a list, and then they take that structure and...they highlight the specific files that the information is going to come from and the specific variable names that are needed and say...exactly what to do.” (P3, epidemiology)

Similarly, participants reported how the use of core facilities, data analysis centers, and what some participants referred to as “recharge” centers served as structures for data management. These centers were used for data analysis, resources provided by the university. These documents and centralized resources are indicators of institutionalization, that is, becoming taken-for-granted and an almost invisible part of the workflow. Participants emphasized how these centralized resources were becoming taken-for-granted, indicating the establishment of more mature systems for data management in their research groups. As P3, described:

“So first off, I think it's important to understand that here at the [University of X] we said we have a Center and it's housed in the school of pharmacy and the center is called Pharmaceutical Research Computing [PRC]. Pharmaceutical Research Computing has a data use agreement for Medicare, a 5% random sample of Medicare data – and that's very common, a 5% sample is a common sample that CMS sells, through their contractor – so the 5% sample is housed over in PRC and they have it for years 2006 through 2018 at this moment. Medicare data tends to lag two to three years; you can't always get your hands on it right away. What PRC has done – and I've been working with PRC for several years – so PRC they're considered to be a 'recharge center,' meaning that they can't technically make money, but what they can do is they can't profit but they earn their money through people like me who get grants and pay them.” (P3, epidemiology)

The taken-for-granted nature of the data processes are evident in a few aspects of P3’s comment – first, that there is a center for research computing specific to the pharmacy school that has been well-established, and is familiar with Medicare data, another centralized data source. Second, the reference to the “very common” standard of a 5% sample indicates that it’s a taken-for-granted standard, one which the community has converged upon. The industry standard for sampling is understood along the division of labor, to the extent that it is codified in procedures, documents, and the technologies for data processing used by the research computing center.

In addition to these taken-for-granted centralized processes, standards, and data handling understandings is a rising trend of using contractors and other means of outsourcing data activities, e.g., for survey data collection. This is in parallel with the contracting of sequencing in genomics, i.e., sending out data for analysis to an external or internal entity. They involved the use of standard procedures, documents (e.g., spreadsheet templates detailing what was needed for the analysis), shared and/or controlled vocabulary. For example, P4, P7, P11, P12 and P14 all reported using contractors for transcription, data processing, or survey research. As P12, a tenured faculty studying survey methodology described:

“So we often use contractors. We pay somebody else to collect the data for us, then they deliver a data set to us that has been de-identified. Everything gets stored on password protected servers only people who have been approved and gone through the IRB training and all of that can get access to those data then, are kept on the servers for the lifetime of the project and then archive as needed for purposes of replication depending on what the project is and the journal, and the grant funding requirements (P12, survey methodology)

Centralized resources also came in the form of funding, where reports documents and entities supporting data management were well-equipped with resources, such as personnel and a budget for research data management. While unexpected and unintended, an outcome of the use of these resources was they provided infrastructure to achieve data management outcomes in the form of ostensive routines. Formal processes, documents, and plans were associated with less data precarity.
“Borrowed” Resources: Adapting Legitimizing Principles for Data Management and Learning from Others

_Borrowed resources_ are the tools, techniques, and materials that faculty researchers adopted to help manage their data. For instance, faculty adapted or reapropriated software (e.g., Dental client database software). They also drew from legitimizing principles, and best practices from colleagues and other disciplines to systematize their data management workflows. Scientists engage in routine infrastructuring to move data closer to repositories by borrowing documents, code, legitimating principles for handling data and other resources from outside disciplines (Figure 1).

Coordinative artifacts (Bardram & Bossen, 2005) like documentation, code, and templates help to move the data by iteratively checking datasets to enable them to be deposited. Faculty drew from standards established by America Speaks, a national survey administrator. As P13, a tenured professor in public health, describes she borrows from other sources to prepare data for deposit by checking for data quality:

> “I did not do all the checks. We are actually working with a survey administrator we had contracted with at a national research Center. They run a panel called America Speaks, which operates and utilizes them on other studies as well. When I got the initial data from them we, to our benefit, inherited many of their protocols and processes for our project, which are guided by best practices and a few other kinds of, not accrediting bodies, but kind of professional oversight bodies. And so, all of that is in the documentation as well as includes some of the details of how their panel is structured should anyone, you know, really want to get into those details of how they create their lists and weights.” (P13, public health)

Similar to P13’s experience with borrowing the “protocols and processes…which are guided by best practices,” P15, a tenured faculty in public health services, used external standards and guidelines as part of her process of checking for data quality. Her process also reflected how she “inherited many of their protocols and process,” but instead of from a professional oversight body, it was from her training as a clinician:

> “The thing that probably influenced me is I came from the clinical trials world where documentation is so tightly monitored. You have auditors coming in and auditing medical charts and study documentation. So that probably influences how I think about documentation a little bit as well.” (P15, public health services)

Likewise, P6 reported that it was a “godsend” that they were able to borrow from a previous project that used similar software, and could inform their data management process: “There was a large study in in criminology that was done before us that used it and that study started in 2000 and continued to like 2007, and so we drew on their experiences from [the prior study]” (P6, tenured criminology faculty). Multiple participants had similar experiences, where they borrowed the infrastructure from previous projects to use in later projects. The systems they put in place, then, created a type of momentum ¿ where important Faculty described learning from other faculty, including mentors and webinars, borrowing the techniques discussed in other fields.

**DISCUSSION & OPPORTUNITIES FOR DESIGN**

Based upon the semi-structured interviews with U.S. academic social science faculty who submitted data to ICPSR, I have determined that scientists draw from three types of resources used to do ‘routine infrastructuring’ (as exemplified in Table 1). The three types of resources served to create supporting infrastructure to manage and deposit their research data: 1) bottom-up resources, 2) top-down resources, and 3) borrowed resources. Perhaps researchers do not rely as much on centralized, formal institutional resources as much as suggested by the explosion of survey studies of researchers’ needs for resources for data management (Akers & Doty, 2013; D’Ignazio & Qin, 2008; Hemsley et al., 2020, p. 202; Sewerin, 2015; Van Tuyl et al., 2015; Whitmire et al., 2015).

**Research Reproducibility: Does the Use of Informal Resources Inhibit Data Provenance?**

Research reproducibility is enhanced by documentation of the data provenance chain, which is made possible by explicating the set of steps taken on the data. Documentation and explicating of data provenance relies on ostensive routines - i.e., the formal rules and the artifacts which encode them – and performative routines – the steps taken to follow the rules for data documentation. Therefore, if researchers borrow or appropriate resources from outside their home disciplines, how applicable are borrowed artifacts and processes? Routine infrastructuring involves improvisation and creative re-appropriation of the tools which are ‘ready-at-hand.’ Yet, improvisation is not easily documented or structured because of its unpredictable, in-the-moment nature, raising the question: Does resource borrowing and improvisation hinder the research reproducibility?

In the study, results showed that researchers “borrow” artifacts, processes, and other resources to enact data management routines. Just as Lee (2007) showed in her development of the boundary-negotiating artifacts, we find that scientists appropriate tools and norms of other communities when the social sciences lack convergence on norms, or when no tools fit social scientists’ data management needs. Because there is a lack of precedent or due to high turnover in academic research projects, data loss is often attributable to research team members leaving – and a
lack of organization or set of rules for the continuity data management, e.g., where it should be stored, who is responsible for it, how it is described, and a contingency plan for backup. Future work in this area can assess whether there is questionable reproductivity, as the interview data suggests. This work can inform recommendations as to develop tools for the community and/or to capture improvisational activities in para data (Dahlström, 2020).

**Beyond Bureaucracy: Does Infrastructuring to Manage and Deposit Data Shape Research Design?**

Recent work in research data management has tried to shift the narrative away from research data as administrative (Wilkinson et al., 2019). However, the interviews and prior literature shows data management is constitutive of research; that is, filling out forms and identifying appropriate metadata scheme are part of data management, and while they may appear *prima facie* as perhaps “mindlessly” bureaucratic, findings from this study suggest data manage is expertise laden, is a learning process with “intellectual content.”

Here, the empirical results add a nuance to existing theory, suggesting ‘routine infrastructuring’ is not only a way to *enact* routines, but one that *creates* routines, which develops momentum that structures future practice. Lee (2007) made a similar claim, arguing that “artifacts can serve to *establish* and *destabilize* protocols themselves.” Specific to the ICPSR context, findings show that routine infrastructuring practices have ‘downstream effects’ – that is, the tools, practices, and conventions that are established ‘stick around.’ As seen with the criminology and epidemiology faculty, the routine infrastructuring done from prior projects form the “installed base” upon which the next projects are structured. This finding that infrastructuring to manage data shapes research has important implications for a perennial concern in the information science literature: how to make scientists data management routines more “mature” – e.g., using a capability maturity model for research data management (CMM for RDM) (Crowston & Qin, 2011). They face publish-or-perish pressures where data products are not foremost in their evaluation priorities.

Moreover, studies show scientists want to do science – seeing RDM as an “administrative task.” Prior studies show that scientists do not want more bureaucracy. But we still lack an explanation for why they reject models like CMM from a social, cognitive, or economic perspective. This study addresses this gap by importing ‘routine infrastructuring’ from the crisis informatics literature to argue that scientists need to adapt policy to their local circumstances; the CMM model underspecifies how to implement research in their local context. The interviews in this study also showed the role of *anticipation* in data management and deposit. If scientists anticipated the deposit of data from the start of a project, they had an “installed base” (Star, 1999) upon which to support data management processes. The scope of this project was limited to describing the resources and routines scientists adopted to manage and deposit data. Future work can build on these insights by identifying the resources that scientists use to deposit and to identify places in workflows where institutional resources fall short, addressing data loss.

**CONCLUSION**

This study investigated the research questions: *What resources do U.S. academic social scientists use in managing and depositing data to research data repositories? What are the implications for FAIR and CARE? Through an analysis of semi-structured interviews with U.S. academic faculty who deposit data to ICPSR, and deploying resource-centric theory from crisis informatics, that of ‘routine infrastructuring,’ I identify three types of resources researchers appropriate to manage and deposit research data. I show how the use of informal resources and resources external to their immediate research group and/or discipline can positively impact FAIR and CARE outcomes – e.g., preventing data loss and enabling participant privacy – but that scientists’ appropriation of outside resources can pose a threat to research reproducibility by impeding the creation of consistent provenance documentation. The three types of resources I developed may be used to inform science policy and create resilient systems for qualitative research data management and deposit to research data repositories such as ICPSR. Given the difficulty in creating resources that will apply to the specifics of every situation of each research study, the concepts presented related to routine infrastructuring and the sharing and repurposing infrastructure and practices is important both from a theoretical perspective and for actual practice in supporting data curation and deposit.*

**ACKNOWLEDGEMENTS**

I would like to thank my writing partners Dr. Elliott Hauser and Yifan Xu for their feedback on early drafts and my dissertation advisor, Dr. Jian Qin, for her support.

ABSTRACT

False information, also known as misinformation or disinformation, has long been a serious concern in health information behavior research. The phenomenon of false information in health information behavior is complex and multifaceted, and it involves a range of factors related to the production, dissemination, and consumption of health information. This paper aims to understand through which channels people receive false health information and which information behavior patterns exist towards this kind of information. Based on 21 qualitative semi-structured interviews with interactive and visual participative elements, five patterns of health information behavior towards the receipt of false health information were identified. Further, a strong relationship between these patterns, the context in which false health information was encountered, and the information source was observed. Additionally, two specific information behavior patterns (information avoidance and intentional non-information behavior) as well as the urgency and impact of false information on the health of individuals and society, were identified as potential drivers for the dissemination of false health information.

KEYWORDS

health information behavior, qualitative research, information avoidance, false health information, misinformation

INTRODUCTION

The proliferation of digital media has led to an exponential increase in available online health information. While this has the potential to empower individuals to take control of their health and to make informed decisions, it also creates new challenges related to the quality and accuracy of health information. False information, also known as misinformation or disinformation, has long been a serious concern in health information behavior research (Karlova & Fisher, 2013). The spread of potentially false or misleading health information can have serious consequences for individual and societal health outcomes, including reduced vaccination rates, increased prevalence of preventable diseases, and a general erosion of public trust in scientific institutions (Dewitz et al., 2022). Previous LIS research has provided less clarity from an information behavior perspective on how people respond or react to false health information. Instead, there are interdisciplinary examples that examine psychological responses to health misinformation, such as factors influencing susceptibility to health misinformation (Nan et al., 2022) and the impact of misinformation on vaccination attitudes (Loomba, 2021). Therefore, the aim of this paper is to better understand from which sources individuals receive false health information and how they respond in different circumstances. Further, the aim is to identify potential drivers that promote or reduce the dissemination of false health information. The phenomenon of false information in health information behavior is complex and multifaceted, and it involves a range of factors related to the production, dissemination, and consumption of health information (Islam et al., 2020). The term false information encompasses both disinformation and misinformation. These two terms differ in the intention behind the creation or (re)sharing of the information. Disinformation refers to false information intentionally spread by individuals or organizations with malicious intent. On the other hand, misinformation refers to false information that arises from unintentional mistakes or misunderstandings. Since it is not always possible to trace the intention in the reception path, the authors of this study use the term false information to encompass both disinformation and misinformation. (Baines & Elliott, 2020).

In certain contexts, false information is more likely to spread, such as on social media platforms, where the algorithms that drive content dissemination may favor sensational or emotionally charged content over accurate and evidence-based information (e.g. Riaz, 2021). This has led to a predominance of studies focusing on social media (e.g. Koohikamali & Sidorova, 2017; Chou et al., 2018; Wang et al., 2019). This study not only focuses on social media as a driver of false health information dissemination but also examines multiple everyday health information interactions of people, which opens up possibilities to investigate behavioral attitudes towards health (false) information from a holistic perspective. This includes interpersonal physical and interpersonal digital interactions.

Despite the growing recognition of the importance of false information in health information behavior, relatively little is known about how individuals perceive and respond to false health information. Understanding the ways in which individuals engage with false information, as well as the factors that contribute to its dissemination and
impact, is essential for developing effective strategies to combat their spread. This paper aims at investigating
people's information behavior with a focus on identifying behavior patterns related to receiving potentially false
health information. For this purpose, 21 qualitative in-depth interviews with interactive participatory elements were
conducted and analyzed using a grounded theory approach with adult individuals between 20-76 years of age.

This paper is structured as follows: in the background section, we describe related works on health information
behavior and false health information. Afterwards, we describe our research design and our results. A discussion on
those results as well as limitations conclude the paper.

LITERATURE REVIEW
Health Information Behavior
Information behavior refers to the various ways in which humans interact with and react to information (Greifeneder
& Schlebbe, 2023). It encompasses the complexity of these interactions, which can involve actively seeking or
passively encountering information through different sources and channels (Wilson, 2022). Humans may engage in
a variety of behaviors related to information, such as seeking, managing, sharing, or even avoiding (Bates, 2017).
Health information behavior examines how people interact with health information, e.g. how people seek, use, avoid
or evaluate health-related information (Johnson & Case, 2012). It encompasses a wide range of studied health
practices in digital and physical environments as well as activities and contexts of health and specific illnesses
(Lambert & Loiselle, 2007). Especially information avoidance is a common phenomenon related to health
information (Sun et al., 2022), which is mainly researched concerning genetic risks (e.g. Bosompra et al., 2000;
Brashers et al., 2002; Cutler & Hodgson, 2003), and diseases, as for example cancer (e.g. Lambert et al., 2009) or
Covid-19 (e.g. Kim et al., 2020; Siebenhaar et al., 2020; Link, 2021, Song et al., 2021; Soroya et al., 2021). Health
information avoidance refers to a phenomenon where individuals actively or passively avoid or delay receiving
potentially unwanted information, which can also include avoidant behaviors (Affifi, 2009; Sweeney et al., 2010).
Studies have shown that health information avoidance can be influenced by a variety of factors, including fear,
stigma, lack of trust in healthcare providers, and negative emotions associated with illness (Howell et al., 2020).
Varieties of information avoidance were identified depending on underlying intentions and embodiments (Golman et
al., 2016). Information avoidance as well as other information behaviors may lead to increased levels of stress and
uncertainty. Kim et al. (2020) state that information avoidance is connected to misinformation and that uncertainty
about information can lead to seeking additional information (sources) as well as serving as a trigger for avoiding
information, similarly to Sun et al. (2022).

In information behavior research, the phenomenon of information sharing or information exchange is widely
discussed (Wilson, 2010; Pilerot, 2012; Savolainen, 2017). Syn and Oh (2009) have explored the underlying reasons
that motivate individuals to share information on social media; these include “enjoyment, efficacy, learning,
personal gain, altruism, empathy, community interest, social engagement, reputation, reciprocity” (p. 559). In
addition, Bao & Bouthillier (2013) identified information sharing as a collective and mutual benefit behavior, which
affects relationships. Individuals who engage with health information may evaluate and filter information to
subsequently share it with others (Tanja & Hansen, 2006) to educate, raise awareness, promote their own beliefs,
share experiences, back up opinions, or demonstrate knowledge (Bao & Bouthillier, 2013). Contrary to this, people
also tend to not share information for various reasons. Huisman et al. (2020) describe this phenomenon as part of
“non-information behavior” (non-IB). They emphasize, in relation to health, that understanding why people do not
share information is essential for understanding the process of how people interact with information and, more
importantly, how people respond to information. Two other relevant concepts for this research in health information
behavior are information resilience (Lloyd, 2014) and information resistance (Kitzie et al., 2021). Health
information resilience refers to information literacy practices for handling situational interferences to existing
knowledge (Montague, 2022). The concept of information resistance on the other hand is focusing on the
counteracting against discursive powers. This concept was identified, for example, by trans-identifying individuals
resisting cultural stereotypes (Huttunen, 2022) or members of the LGBTQIA+ community imagining alternative all
embracing information worlds, including themselves (Kitzie et al., 2021). For the purpose of the analysis, we will
use the broadest term intentional non-IB, which encompasses all facets of non-sharing, resistance and resilience.
This term should be further discussed in the IB community, as the phenomenon is a refusal behavior that differs
from other avoidance behaviors in IB research. For clarification, non-IB implies that the decision not to engage with
information also involves a conscious behavioral intention.

False and Misleading Health Information
As Nguyen et al. (2023) demonstrate on the basis of a systematic literature review over the last 12 years, false
information, referred to as misinformation, has already been studied on health matters in our field, focusing on
vaccination concerns, healthcare risk management, medical treatment and Covid-19. The internet and social media
have made it easier for people to access a vast amount of health information (Fox & Rainie, 2002), but at the same
time it challenges people's abilities to evaluate and make sense of the health information received in form of
information literacy (e.g. Pian et al., 2016; Huo et al., 2018, Chi et al., 2020). This became especially apparent during the Covid-19 pandemic (Islam et al., 2020). Tandoc et al. (2018) have proposed that being exposed to false information can prompt individuals to seek out more information in order to verify its accuracy. This can lead to individuals seeking out information from their social circle or other sources to confirm the validity of the information, particularly if they are unable to judge the source of information based on their own knowledge or to correct their understanding of a particular topic (Lewandowsky et al., 2012).

Factors that motivate individuals to share accurate information, such as emotional resonance and personal relevance, are also likely to be the same drivers that contribute to the widespread sharing of false information (Allington et al., 2021). According to the findings of Chen and Sin (2013), individuals primarily share misinformation with the objective of seeking opinions of others, expressing their own views, and engaging with other people. Emotions also play a role, because information that triggers high emotions, both negative and positive, is shared more often than information without an emotional dimension. In addition, despite the distrust in misinformation, various motivations for sharing, including entertainment, sarcasm, and education were identified by Metzger et al. (2021). Buchanan (2020) further found that individuals who encounter false information on social media often actively propagate it by sharing it, regardless of their level of digital literacy. Those who believed the false information to be true or had pre-existing attitudes that aligned with it were most likely to share it. Further Zhao & Tsang (2022), who analyzed the sharing intentions of individuals, identified a strong link between the content and falsity of false information and the tendency to share it.

The Covid 19 pandemic was accompanied by a mass of false and misleading information and evolved into an overabundance of evidence-based but also false information (World Health Organization, 2020). This so-called “infodemic” brought to light the controversial nature of the topic of health. This was particularly evident in the context of health decisions that had to be made on the basis of health information, e.g., the decision to get vaccinated (Allen et al., 2023). This issue persists and represents a significant obstacle to the advancement of public health. One particularly important area of study in recent years has been the phenomenon of how false information beliefs can be combated through information literacy (De Gani et al., 2022). While many studies have explored how people encounter and process false information (Rapp & Braasch, 2014), relatively little research has been done on the information behavior of individuals after receiving false health information.

RESEARCH DESIGN

Aim of the paper
Understanding the ways in which individuals engage with false information, as well as the factors that contribute to its dissemination and impact, is essential for developing effective strategies to combat their spread. This paper investigates people's false information behavior in regard to their health with a focus on identifying patterns of behavior related to receiving potentially false information. The two research questions for this paper are the following:

RQ1 : Through which channels do people receive false health information?

RQ2 : Which information behavior patterns are used by individuals as response to the receiptment of false health information in physical and digital environments?

Method
The DESIVE project, which aims at understanding dis- and misinformation behavior, is a three-year project (2022-2024) funded by the German Federal Ministry of Education and Research. The project triangulates data from qualitative explorations through interviews, app diary entries and surveys (https://desive2.org/). As part of the project, 21 qualitative semi-structured interviews were conducted between September 2022 and January 2023. The study uses a grounded theory approach which makes use of the elements of theory-based sampling, constant-comparison-analysis and theory development (Glaser & Strauss, 1967). Participants were recruited based on project-related events and presentations. A strategic approach to recruitment is necessary to achieve diversification of the sample in terms of socioeconomic parameters, age and gender, which was achieved through regular iterative considerations between the authors of the paper. The sample consisted of 21 individuals (female = 13; male = 8) aged 20 to 76 (7 participants under 30, 9 participants between 30 and 50 and 5 older than 51), living in Germany. Participants in the study received a monetary incentive of EUR 30 for their participation in the study. The ethics board of the faculty of Humboldt-Universität zu Berlin gave formal approval of the study and all participants signed an informed consent. Interviews were held online via the video conferencing platform Zoom and lasted between 31 to 97 minutes, with an average length of 62 minutes. All interviews were conducted by two project members in German, quotes were translated to English after the analysis. The interview guide was pilot tested in four interviews and small changes were made afterwards.
During the interviews, the first step was the identification of participants' health information infrastructures. Information sources and exemplary scenarios of information interactions in the context of health and false health information were examined as well as the trust in all identified sources. Subsequently participants were asked about their personal health information behavior towards false health information. The interviews contained a visual interactive participatory element, comparable to the concept of information horizons (Sonnenwald et al., 2001). Miroboards were prepared in advance on miro.com by the interviewers, a completed example map is given in figure 1. Screensharing enabled all participants to see their personal health information infrastructures without the need to understand the platform and its functionalities. They only verbally influenced the creation process; all technical actions on Miro were done on the interviewers side. During the interviews the boards were filled in and constructed based on the statements of the participants (see figure 1). The generated maps provided a helpful reference point for the rest of the interviews and helped to guide the discussion towards more detailed and insightful questions. Every map is individual and looks different based on explanations and experiences of the participants.

![Figure 1. Personal Health Information Infrastructure of Participant P17 (Miroboard - Example).](image)

The interview data was transcribed in a two-stage approach. First all interviews were transcribed automatically using the software Amberscript. Afterwards all transcripts were verified and reviewed manually by the interviewers. For the analysis of the data a Grounded Theory Approach was conducted. Using Maxqda, the initial coding process was conducted inductively by two researchers, starting with in-vivo and open coding which in a next step were sorted and organized in a focused coding process (Charmaz, 2014). For the qualitative analysis, visual tools of Maxqda as for example the Code-Relation-Browser or the Code-Matrix-Browser were applied.

**RESULTS**

Our analysis of various health information infrastructures, such as institutional and interpersonal entities, enabled us to identify channels that facilitate the exchange of health information. Health information, in this context, includes receiving accurate, and potentially false health information. Health information behavior patterns in regards to false health information depending on information sources and its characteristics were identified and will be discussed below.

**False Health Information in Personal Health Information Infrastructures**

People receive health information from various sources by actively or passively seeking and encountering information or by communicating with others, e.g. family members or professionals, about health. The combination of all channels that serve as information sources for an individual constitute the personal information infrastructure. This study focuses solely on the individual’s health information infrastructure.

The findings of this study indicate that the sources and actors involved in personal health information infrastructures encompass individuals from social environments (e.g. family members and friends), the professional environment (e.g. work and education), (social) media and the Internet (e.g. certain websites). Further educational, health, or research institutions, health insurance companies, and public (health) authorities are part of their infrastructures. In addition, most participants stated that information exchange and communication with others about health-related issues play a central role in the acquisition of individual and socially relevant health knowledge. Participants sometimes refer to misleading health information (e.g. information is wrong in a specific context) while talking...
about their experiences with false health information. In the following, the term false health information is used equally for both misleading and potentially false health information. While two participants were not able to remember a situation in which they received false health information (P13, P6), all other 19 participants shared personal experiences. A collection of all sources and actors, from which participants received false health information is represented in table 1.

Table 1. Participants Health Information Channels Where False Health Information was Received (or not).

Although it was not planned as central component of this study, Covid-19 experiences (P1, P5, P7, P16, P17, P20) or related topics such as mandatory masks (P21), PCR-testing (P9) and vaccinations (P4, P8, P9, P10, P17) were primarily mentioned in combination with the receipt of misinformation. Further false information about diseases (P16, P11), vaccinations independent of Covid-19 (P14) and the use of natural remedies (P2, P20) or alternative health products (P20, P18) were shared.

Regarding individuals in their personal environment, several participants mentioned a lack of information literacy skills, which resulted in the dissemination of false health information (P5, P8, P12, P20). Moreover, the false health information that is shared is often based on a misinterpretation of scientific studies (P8, P20, P21) and lack of understanding (P5, P19, P20), causing it to be believed, not recognized and forwarded (P21).

**Information Behavior Patterns in Response to False Health Information**

After analyzing sources of information sharing and the reception of false health information, information behavior patterns in response to false health information were identified in physical and digital environments. Among other factors (e.g. trust, personal traits, relationship), the handling of the situation and the information behavior of participants seems to vary depending on the channel from which false health information is obtained. Similar behaviors occur in all identified environments, sometimes with small differentiations. An overview about identified patterns in response to receiving false health information is given in table 2.

</tbody>
</table>

The information behavior patterns varied the most in the personal environment of the participants depending on the sharing person (e.g., family members, friends, acquaintances). Receiving false health information from acquaintances often leads to discussions (P7, P14, P17) or in interrupting the sharing person (P20). Towards colleagues at work intentional non-IB or avoidance is rather reported (P12, P19). Participants restrain their opinion (P19), or ignore the situation after unsuccessful clarification attempts in the past: “It's just like conspiracy theories. You just don't accept it anymore. You ignore it.” (P12). In response to false health information from family and friends, participants are more willing to evaluate the information by critically questioning sources and references (P17, P18) or seeking information afterwards (P1, P16, P17, P18, P19). Additionally, in personal conversations or discussions, individuals may share validated counterarguments (P1, P5, P8, P5, P20, P21), seek information (P1, P8, P16, P17), or offer opinions (P20) in order to clarify false health information. One participant mentioned supporting family and friends in their handling of false health information by explaining:

“Look, where did it come from? Who wrote this? What could be the intention of the person or persons to claim or not to claim this? What did they claim before? Things like that, to somehow classify this long-term.” (P5)

Continuing disagreements in personal conversation or discussions result in two behavior patterns towards family and friends: avoiding the topic because of conflicting opinions (P8, P21) or trying to understand the origin leading to the acceptance of different opinions (P4, P8). These different behaviors can be attributed to closeness and mutual trust (P4, P8) or the wish to stay in contact with family members (P8, P21). If opinions were too different in friendships
on the other hand, breaking off contact in response to receiving false health information was identified (P10, P21). This has been particularly relevant in relation to the Covid-19 pandemic:

“I thought it was remarkably different, because normally Person A has an opinion and person B has an opinion. And then you have different opinions and that's where it stays. But I had the feeling that with Corona it was somehow a question not only of one's attitude, how one wants to behave or of one's convictions, but that these convictions can have an influence on others. Much more concrete than if it is about whether the person now believes in God or not. So there are other areas where someone can believe something different than me or be convinced of something different than me. But it doesn't directly affect my health. So that was kind of new, I thought.” (P17)

Intentional non-IB and information avoidance were two information behavior patterns that we observed in response to false health information. Intentional non-IB means that participants decided not to react to the false information, for example, not discussing it, not explaining it, not agreeing or disagreeing with it. Unlike information avoidance, the person continues to listen to and does not avoid the topic or the person altogether. However, once the information is received or heard, the person consciously decides not to react to it, as explained by P10 in a conversation about alternative healing methods instead of cancer treatment:

"I just listened and didn't agree and didn't speak against it because I didn't think I needed that kind of discussion.” (P10)

Referring to digital environments (e.g. instant messengers, social media, internet), this behavior occurred concerning false information during the Covid-19 pandemic. In large group chats with various people from the same sports club (P8) and when encountering false health information on the Internet (P20) or social media (P4, P16, P17) participants decided to not behave in a certain way:

"But I don't necessarily see telling strangers over the Internet that they're talking nonsense as effective. It has, it can have an effect. But I think it's often more likely to cause ignorance.” (P20)

A summary of all identified reasons for situations, in which participants intentionally decided to not behave in response to false health information is given in table 3.

</tr>
<tr>
<td></td>
<td>“And when people just argue that way, I say, there's not much I can do about it. Instead of saying: 'Look, if you get sick, it may be worse.' if the person has come through two years of Covid completely unscathed [...] yes, what else do you think? It becomes difficult. You can only decide for yourself what is important for you.” (P1)</td>
</tr>
</tbody>
</table>
DISCUSSION

The aim of this paper was to understand through which channels people receive false health information and which information behavior patterns exist towards this kind of information. Based on our results, the spread of false health information was predominantly identified in physical face-to-face conversations with family, friends and colleagues, as well as in digital environments such as (group) chats and social media. Although health information behavior is individual, patterns towards false health information were identified among the participants, which include for example information seeking, evaluating, sharing and avoiding. It became evident that comparable patterns occur in both physical and digital environments. For this reason, it is useful to emphasize the intertwined and standalone characteristics of both digital and physical environments as part of future research on false health information. Furthermore, the influence of patterns in both environments needs to be analyzed regarding their comparability. Due to factors such as the speed of propagation and the wide range of possible recipients, the extent of some patterns could be more severe in the digital environment. Typical health information behaviors defined by Johnson & Case (2012) consequently occur also towards false health information. Two information behaviors appear to be important drivers for the dissemination of false health information: information avoidance and intentional non-IB.

Zhao & Tsang (2022) indicated that the content and especially the extent of falsity of false information is a driver for its dissemination. This was only visible in very few cases in our study. Instead, the context and source from which false health information is encountered are crucial. Information behavior patterns towards false health information are significantly influenced by personal context factors such as relationships, personality traits, and trust. Close relationships, such as those with family and friends, and a mutual sense of trust tend to lead to constructive discussions, where individuals are more willing to accept contradictory opinions and seek to understand and clarify them. Moreover, a distinction between personal and impersonal discussion settings was evident. When false health information is shared by a stranger in an impersonal setting (such as a political protest) or a professional context (such as work or education), individuals are more likely to choose not to engage with it and may even resort to information avoidance. In the context of false health information, no information evaluation or validation occurs. The lack of negative feedback therefore does not minimize the dissemination of false health information. Consequently, information avoidance can be seen as a potential driver.

Unlike in other studies related to health, the information avoidance observed in this study is not a deliberate or unconscious defense mechanism against potentially harmful information (e.g. Sun et al., 2020, Soroya et al., 2021, Howell et al., 2020). Avoidance of false health information only occurs if the health information was identified as false and unwanted. As individuals are already aware that the information is false, it is not expected to cause any

harm as long as it is not shared for entertainment or sarcasm reasons (Metzger et al., 2021). Furthermore, this study shows that information avoidance cannot be attributed to commonly identified drivers such as uncertainty (e.g. Case et al., 2005; Sairanen & Savolainen, 2010), stigma and lack of trust in healthcare providers (Howell et al., 2020) or required, undesired actions (Sweeney et al., 2010; Dwyer et al., 2015; Song et al., 2021). Instead, information avoidance within this study can be equated with the need not to receive information that is considered incorrect and therefore does not correspond to one's worldview or opinion on the specific health topic. This type of information avoidance is referred to as dissonance information avoidance (Chater & Loewenstein, 2016, Golman et al., 2016). Similar to Afifi (2009) and Dai et al. (2020), information avoidance is not limited to information as entity but also to avoiding behaviors that result in the avoidance of receiving information (e.g. unfriending, blocking etc.) to regain control by curating ones’ own information infrastructure. Additionally, actively avoiding false health information seems to be linked to the avoidance of aversive emotions (Siebenhaar et al., 2020). Emotions therefore seem to be not only a driver for information seeking (Savolainen, 2014) but also for information avoidance. Another driver for the dissemination of false information is a related behavior pattern defined as intentional non-IB. In certain scenarios, individuals may deliberately opt not to react in response to false health information. This behavioral pattern tends to emerge in situations in which engaging in a discussion with the person disseminating inaccurate information would yield no benefit or meaning or could potentially harm one's mental well-being or damage the current relationship. In some cases potential aggressiveness of the sharing person(s) or lack of knowledge towards the discussed topic result in this behavior pattern. Intentional non-IB seems to be a filtering mechanism (Talja & Hansen, 2006), which results in filtering false health information without marking it or acting on it. Intentional non-IB also seems to be different from information avoidance. Contact, conversation, or receipt of information are not avoided (which can be both active and passive), instead, a conscious decision not to react or behave towards the information follows. In the context of false health information, it is consequently neither corrected nor supported but also not avoided. To the authors knowledge, this behavior pattern has not yet been studied in comparable information behavior research besides information non-seeking (Manheim, 2014) and information non-sharing (Huisman et al., 2020), and would be interesting to analyze in other contexts as well. It is worth exploring whether intentional non-IB can be considered a type of information resistance (Kitzie et al., 2021, Huttunen, 2022) or information resilience (Lloyd, 2014; Montague, 2022), because individuals do not always have to resist or handle discursive powers in situations where they consciously decide not to react to false health information. However, similarities to both concepts are apparent.

In contrast to Kim et al. (2020) and Sun et al. (2022), who identified information avoidance as potential transition to information seeking, in this study the health information behavior ends after information avoidance. The same applies to intentional health non-IB. Both behavior patterns mean that the person who shares false information does not receive a negative response to the information shared. Consequently, there is no evaluation and clarification of the false health information. If people with similar opinions subsequently receive this information, or people who cannot classify it, for example due to ignorance or uncertainty, the falsity of the information is not revealed. This results in the further dissemination of false health information, regardless of the intention of the person sharing. Accordingly, information avoidance, as well as intentional non-IB appears to be a critical driver for the dissemination of false health information. Link (2021) identified a similar connection between information avoidance and the dissemination of misinformation on Covid-19. In regard to the dissemination of false health information, this warrants attention in future research.

Although false information on health matters has received limited attention in information science, the Covid-19 pandemic has prompted an increase in research on the impact of false information on health (Nguyen et al., 2023). The Covid-19 pandemic, which began in 2020, has brought the issue of false health information to the forefront of public consciousness, making it relevant to all members of society. Although this study did not focus exclusively on Covid-19, it was frequently mentioned as an example for the receipt of false health information. However, other topics, such as chronic diseases, homeopathy, (alternative) pharmaceuticals, and nutrition were also mentioned. The study identified a relationship between the urgency, importance, and prevalence of false health information, and how individuals respond to such information in terms of their information behavior. If shared information has an impact on the society and could potentially lead to a serious or fatal impact (on someone's health), participants are more willing to behave towards this information in form of discussions or the sharing of validated counter arguments, as well as increased information evaluation and health information literacy activities. In particular, the possible influence of false information on one's own health or the health of others seems to determine how participants behave towards it. In this context the content of the false health information influences the behavior pattern towards it, similar to Zhao & Tsang (2022). If the influence is assessed as low, negative feedback on the false health information is less likely to occur, because individuals avoid or do not react to the information. Consequently, the false health information is not questioned, which, in addition to trust in sources (Boutron et al., 2019, Buchanan, 2020), potentially lacking information literacy (Karlova & Fisher, 2013, De Gani et al., 2022), similar beliefs and personal relevance (Buchanan, 2020, Allington et al., 2021) as well as misinterpretations or lack of knowledge, can
promote the spread of false health information. However, it should be noted that this hypothesis may not apply universally in all cases because, for example, during Covid-19, despite the social relevance and need for correct information and the potential dangerous impact, much false information was distributed. In this exceptional situation, however, other factors such as overload, information avoidance and distress also have to be considered, as Siebenhaar et al. (2020) indicates.

LIMITATIONS AND FUTURE RESEARCH
This study has limitations regarding its sample and research design. Except for four, all participants had a higher educational background. Although no significant differences in the behavior towards false health information and information literacy skills were identified, re-recruitment for follow-up studies are intended. Furthermore, the research design of qualitative in-depth interviews is not ideal for the analysis of the person’s false information sharing behavior. Instead, participants tend to report on the information sharing behavior of others and how they react to it. For this study, it has not resulted in negative implications but for future research this ought to be considered.

All participants were aware of the existence of false health information and most participants were able to report experiences. They also referred to information literacy skills, which helped them handle false information. Nevertheless, because of the participants' self-reports, it cannot be assumed that everything they perceived as false health information was false, and everything that they reported as accurate information was accurate. An experimental study that is built into the qualitative design could be used to further investigate the individual understanding of false health information.

CONCLUSION
This study examined how individuals perceive and respond to false health information. Qualitative semi-structured interviews with 21 participants revealed various patterns of health information behavior, and a strong relationship was observed between these patterns, the context in which false health information was encountered, and the source of the information. Factors that influence the health information behavior are the personal context such as relationships, personality traits and trust.

Most information behavior patterns (seeking, evaluating, discussing and sharing) seem to minimize the dissemination of false health information, if they are used to identify and clarify false health information. None of the participants mentioned sharing false health information themselves, which can be explained by the research design. However, based on the identified information patterns, two potential drivers for the spread of false health information were apparent. First, information avoidance and intentional non-IB seem to promote the dissemination of false health information, due to the absence of clarification and subsequent continuous potential spread. Second, the assessment of the urgency, personal and societal relevance, and potential impact of false health information was found to be a significant driver in its dissemination. However, this driver of dissemination seems to be linked to other phenomena such as information overload, information avoidance and distress. False health information can have serious consequences for individual and societal health outcomes, and addressing the drivers of dissemination is an essential step towards curbing its spread.

Understanding Reactions in Human-Robot Encounters with Autonomous Quadruped Robots

Hauser, Elliott  The University of Texas at Austin, School of Information, USA  |  eah13@utexas.edu

ABSTRACT
Incidental human-robot encounters are becoming more common as robotic technologies proliferate, but there is little scientific understanding of human experience and reactions during these encounters. To contribute towards addressing this gap, this study applies Grounded Theory methodologies to study human reactions in Human-Robot Encounters with an autonomous quadruped robot. Based upon observation and interviews, we find that participants’ reactions to the robot can be explained by their attitudes of familiarity, certainty, and confidence during their encounter and by their understanding of the robot’s capabilities and role. Participants differed in how and whether they utilized opportunities to resolve their unfamiliarity, uncertainty, or lack of confidence, shedding light on the dynamics and experiential characteristics of Human-Robot Encounters. We provide an emerging theory that can be used to unravel the complexity of the field as well as assist hypothesis generation in future research in designing and deploying mobile autonomous service robots.

KEYWORDS
Human-Robot Encounter; Human-Robot Interaction; Quadruped Robot; Autonomous Robot; Grounded Theory

INTRODUCTION
With the proliferation of robotics technologies, especially in businesses using robots to facilitate operations (Rindfleisch et al., 2022), encounters with robots in everyday life environments are becoming more frequent. Despite all the benefits provided by robots, reported hostile reactions to robots and robot bullying indicates that there are underlying issues with robot deployments. For instance, in 2014, Smith and Zeller (2017) deployed a hitchhiking robot called hitchBOT to investigate human reactions to it. HitchBot successfully hitchhiked across the world in several trips, however, in 2015, it was found vandalized when it attempted to travel across the U.S. The vandalism against hitchBOT was an unfortunate event and posed a grand challenge to both robotics scientists and Human-Robot Interaction (HRI) researchers: How do humans handle robot encounters in everyday life environments?

To start answering this question, HRI researchers have begun to explore Human-Robot Encounters (HRE). As an emerging research topic of HRI, HRE studies the implicit and indirect interactions between humans and robots when both parties unintentionally encounter each other in everyday life environments. “Many people affected will in fact not be users of robots but will just ‘happen to be there’” (Rosenthal-von der Pütten et al., 2020, p.1) As HRI studies tend to focus on direct interactions, HRE broadens the scope of HRI research by incorporating other forms of interactions. For example, a college student who is walking on campus encounters a delivery robot walking toward her. In this case, HRE researchers may study how she perceives and reacts to the robot without her actually using it. The interaction between the spatiotemporal co-located student and the robot is subtle, indirect, unintentional, and yet socially profound. The student’s perceptions and reactions to the robot are likely to be influenced by factors such as the social cues presented by the robot, the physical environment surrounding them, and the student’s social judgment of the robot (Babel et al., 2022). Currently, many organizations adopt quadruped robots for deployment to utilize their enhanced mobility and the ability to carry objects. Their navigation and autonomy capabilities allow them to generate multiple human-robot encounters. However, past studies and news articles showed that the deployment of quadruped robots had received public criticism, and evoked fear and ethical concerns (Yunus & Doore, 2021), indicating there were challenges to wide and comprehensive robot deployment as well as the need for more HRE research.

Given the complexity and understudied nature of HRE research, this study applies Hoda’s Socio-technical Grounded Theory (2021) to explore how people react to encounters with Boston Dynamics Spot, a quadruped robot. Grounded Theory methodology is well-suited to study HRE because of HRE’s rich social nature, and the methodology can be used to analyze the data collected and generate a theory to explain HRE as a sociotechnical phenomenon. We apply participatory observations in a lab-based HRE study and conduct semi-structured interviews to collect in-depth data. Following Hoda’s guidelines (2021), the present study is preliminary and small-scale, and the data collected is not comprehensive enough to generate a mature theory. Therefore, this study focuses on providing an emerging theory that explains the data collected so far and can be used to generate hypotheses in future research. Our emerging theory proposes that human reactions to an autonomous quadruped robot in an HRE scenario are associated with humans’ familiarity, certainty, and confidence in encountering robots.
RELATED WORK
Following Hoda (2021), we conducted a lean literature review before the study, and a targeted literature review after data analyses (p. 14). In this section, we present the works that serve as the basis of our study.

The fast development and deployment of robotics systems in human society increase the chances of humans unintentionally encountering robots, therefore it is of paramount importance to understand this emerging phenomenon. Due to technology limitations, early works on HRE relied heavily on observations and wizard-of-oz setups. Additionally, these works focused more on what people think and behave prior to the actual and direct interactions, and then proposed recommendations to improve interaction quality in general. For instance, Bergstrom et al. (2008) conducted a field study, observed how people react to a humanoid robot in a mall, and classified the people into groups of Interested, Not Interested, Indecisive, and Hesitant based on their speed, orientation, and position. The authors further examined the effect of different types of robot behavior on perceived naturalness and concluded that the match between robot behavior and the type of people would allow them to perceive the robot as more natural. Even though the main focus of this study was not on HRE, it did emphasize the importance of understanding human behavior that was prior to direct interactions. In a recent work on Social Robotics, Avelino et al. (2021) explored the literature on social robots’ greeting abilities in encountering new users in a social context. The authors emphasized the importance of first impressions and the development of robot capabilities that would lead to a better experience for new users. The authors also pointed out that future research on Social Robotics should examine how non-verbal communication between robots and humans can lead to better encounter experiences. Both of the reported studies are not HRE research, but they contributed knowledge to different aspects of HRE.

HRE research is expanding but the dearth of it means that it is still understudied. To answer this challenge, Babel et al. (2022) adopted a box-like cleaning robot and deployed it in a busy train station. The authors recruited people who walked past the robot and asked them to answer a questionnaire. They also observed and interviewed the people. Their results showed that people had concerns about collisions between robots and pedestrians, job loss, and inconvenience caused by the robot’s lack of communication capabilities. This study provided empirical findings about human reactions to an autonomous robot in public. However, robot vacuums have been available to the public for several years, so people might be more familiar with cleaning robots in general. This leaves the question that if people would react to a more technologically advanced robot in the same way. In one of the most recent works on HRE, Moesgaard et al. (2022) conducted ethnographic research to study how people would react to a primitive mechanoid robot that did not follow social norms. Their results indicated that people not only utilized their prior knowledge of robots and robots’ behavior to evaluate them, but also drew upon membership categorization frameworks to make sense of them. The authors emphasized the notion of humans and robots will soon come to co-exist in this world, and HRI research should expand beyond the idea that humans are only direct users of robots, as more and more research has touched upon the indirect interactions between humans and robots. Furthermore, the authors argued that robotics system designers should not only focus on the capabilities of robots but also on how people feel about them, especially in public settings. This argument also implied that HRI researchers should take into account the rich social nature of HRI and HRE in future research. Another HRE work by Hardeman (2021) used a wizard-of-oz setup and conducted field research on 28 people who walked past a wheel delivery robot. The results were similar to Babel et al’s (2022) work where people showed concerns about collisions, privacy issues, and the lack of communication capabilities. The topic of this study was similar to our research; however, this study was exploratory in nature and also adopted a primitive robot. Nevertheless, their results seemed to show that people had neutral to positive reactions to the robot.

HRE research is still nascent. The reported works have studied how people perceive and react to robots that they accidentally encounter. However, those works investigated HRE by focusing on how people react to a robot in general, without taking into account the appearance and capabilities of the robots being used. In other words, it is still unclear whether their findings would apply to other types of robots as well as if there were any hidden factors. As presented by Babel et al. (2022), the authors investigated human-robot conflicts using humanoid, zoomorphic, and mechanoid robots, and found that human compliance and acceptance differed between the robots. We argue that the zoomorphic form of Boston Dynamics’ Spot may elicit different human cognitive and behavioral responses. Additionally, since the public sale of Spot in 2019, it has received mixed reviews from the public on major social media. A sentiment analysis of Twitter conducted by Moses and Ford showed (2021) that on the one hand, people were amazed by the technology, on the other hand, the dog-like robot’s connection to military use scared many people. Most people had not seen dog-like robots in real life and their perceptions of them mainly originated from the impressions of them from watching online videos, movies, and TV shows that showcased robot dogs. The authors called for more research on this topic. To the best of our knowledge, no research has studied how people react to an autonomous quadruped robot when they accidentally encounter one. Therefore, we aim to fill this gap by using Grounded Theory methodologies to explore human reactions to an autonomous quadruped robot and propose an emerging theory that can be adapted to generate hypotheses in future research.
METHODOLOGY
This research followed Hoda’s (2021) Socio-technical Grounded Theory. The site of our study was a lab-based HRE study that investigated human perceptions of a quadruped robot (Hauser et al., 2023). We conducted participatory observation while assisting in the data collection for the HRE study, and interviewed the participants to understand their experiences in the study. This work presents our analysis of the experiment and interview data, fieldnotes, observations, and a variety of other sources, such as the original experiment protocol and interview guide.

Detail of the Study Site
A total of 21 participants were recruited from a local university through an email list. Eight of them identified as male and 13 of them identified as female. Seven were undergraduate students and 14 were graduate students. The participants’ majors included Information Studies, Computer Science, Latin American Studies, Biochemistry, and Biomedicine Engineering.

The HRE study consisted of (1) a lab-based experiment, (2) a survey, (3) a free-form interaction session with the robot, and (4) an interview. The robot adopted in the experiment was the Boston Dynamics quadruped robot Spot. In the experiment, participants were asked to walk from one end of a simulated hallway to the other end (Figure 1). Meanwhile, the robot was programmed to autonomously walk from the opposite end to where the participants were standing. The participants and the robot would encounter each other roughly in the middle of the hallway. The robot was programmed to avoid the participants autonomously and then keep walking to the destination. The participants were not notified what would happen in the hallway and were only instructed to walk freely and pass the robot however they felt natural. There were two conditions in the experiment, namely Leashed, and Autonomous. For the Leashed condition, a research team member walked together with the robot, holding onto a leash that was tied to it (the robot still walked autonomously). For the Autonomous condition, the robot walked by itself without the leash or and presence of the research team member. The Leashed condition was designed to test whether the presence of a human and canine behavior visual cue would influence the participants' reactions (see Hauser et al., 2023 for more detail). After the experiment, the participants were asked to answer a survey regarding their perceptions of the robot. The free-form interaction session came after the survey. The participants were offered a chance to interact closely with the robot, take photos or videos of it, and ask any questions they might have to the research team. They were also offered opportunities to see the robot perform additional tricks such as sitting down and dancing. After this session, the participants were instructed to join the interview.

Figure 1. The simulated hallway, both the robot and participants walking in it.

Interview
The interview was semi-structured and consisted of seven core questions, including (1) the participant’s experience in the hallway, (2) the influence of the presence of humans, (3) the participant’s experience in the free-form interaction session, (4) the participant’s speculation of their reactions to the robot in non-laboratory settings, (5) improvements to the robot, (6) the participant’s familiarity and prior experience with robots, and (7) the participant’s speculations of the robot’s purpose in the study. The interview was supplemented with follow-up questions that were prompted by both the participant’s answers and the researcher's observations. The first round of interviews (12 participants) lasted around 20-25 minutes and included only the first six core questions. As data collection and analysis happen simultaneously in Grounded Theory studies, we identified a prototypical question “What is the
robot doing here” that was commonly raised in the first round of interviews. Therefore, we decided to add the 7th core question for the second round of interviews, which lasted around 25-40 minutes.

**Data Analysis and Source**

We adopted an integrated data collection and analysis process, which is characteristic of Grounded Theory methods. During the data collection process, the authors reviewed the interview data collected and conducted the initial analysis with open coding and constant comparison. The categories that emerged from the data prompted us to adapt the interview protocol as mentioned in the section above. The participant recruitment ended when we reached theoretical saturation. After the data collection was finished, we conducted iterative data analysis. We first coded participants’ reactions in different phases of the HRE study, and then we coded what influenced the participants’ reactions. The coding and constant comparisons were conducted iteratively until the theoretical categories emerged. Finally, we conducted memoing to document our interpretations of the theoretical categories which were the reactions in relation to familiarity, certainty, and confidence in encountering an autonomous quadruped robot.

Ongoing participatory observation in robotics research guided the author’s interpretation of these findings. The authors recorded and discussed their experiences in assisting with the administration of the HRE study protocol. These experiences prompted follow-up questions for the interviews and informed the interpretation of the interview data as well. Iterative writing, analysis of fieldnotes, and basic memos all guided integrated data collection and analysis.

**FINDINGS**

We first describe the participants’ reactions to the robot. After presenting and illustrating these, we focus on moments where participants described changes or shifts of reactions. Then we analyze the reactions and changes in terms of familiarity, certainty, or confidence, find patterns within participants along these facets, and propose and explain in detail our emerging theory: Human reactions in encountering an autonomous quadruped robot are influenced by their Familiarity, Certainty, and Confidence. (Figure 2). Finally, we describe the phases of the HRE study protocol in terms of the opportunities they present to the participants to increase their familiarity, certainty, and confidence in encountering an autonomous quadruped robot.

![Diagram](image.png)

**Figure 2.** Our emerging theory: Human reactions in encountering an autonomous quadruped robot are influenced by their Familiarity, Certainty, and Confidence.
Participants’ Reactions
This section briefly describes the participants’ reactions we saw in our data. In the following sections, we elaborate on what influenced participants’ reactions and why there were changes in reactions. All participants expressed that they were generally curious and excited about robots, so they wanted to learn more about robots by participating in this study. As for their first impressions of the robot, the participants reacted as surprised, scared, cautious, curious, and not surprised. There were two major inflection points when participants’ reactions changed, including (1) the moment when they realized the robot would avoid them in the hallway (i.e. the encounter), and (2) the free-form interaction session. These inflection points made participants who were initially scared or cautious feel relieved, surprised, more comfortable, or become curious and impressed, whereas participants who were initially curious or surprised stayed curious or became excited and impressed. After our coding and constant comparisons of all interview data, the changes in reactions appeared to be the results of changes in familiarity, certainty, and confidence in encountering the robot. During the inflection points, several opportunities were utilized by the participants that helped them gain more familiarity, certainty, and confidence in encountering the robot. These were accomplished by having a better understanding of the robot’s capabilities and role, as well as the increased mental proximity between the participants and the robot.

The Relationships Between Reactions, Familiarity, Certainty, and Confidence
This section details our emerging theory characterizing human-robot encounters in terms of participants’ familiarity, certainty, and confidence. We first describe what influenced the participants’ reactions and how the reactions relate to familiarity, certainty, and confidence. Participants’ initial reactions were influenced by their prior experiences with robots and their first impressions of the robot’s capabilities, including its appearance, walking, the sound of footsteps, and cameras. Many participants were unfamiliar with the robot, uncertain of what was going to happen, and were not confident enough that it would be perfectly safe to walk to the other end of the hallway. After the encounter, some reported becoming more certain and confident of their understanding of the robot’s purpose. In the free-form interaction session, they also increased their mental proximity to the robot by being able to touch it and get close to it. These opportunities helped the participants gain familiarity, certainty, and confidence in encountering the robot. The participants also reported that the presence of a human afforded them a sense of familiarity, and more certainty and confidence that the robot was safe.

Prior Experience with Robots
Participants’ prior experience with robots influenced their first impressions of the Spot platform. Every human has their own prior experiences, familiarity, or associations with robots. To some people, encountering a robot may be as normal as encountering a car. To others, a robot may appear as an out-of-this-world species. Even though encountering robots is still uncommon for most people nowadays, some participants reported that they had seen dog-like robots in movies or TV shows before. Yet interestingly, their reactions differed. Some participants had seen dog-like robots before and they were curious about the experiment. “I’ve seen such a form. So I was just reminded of them. And I was really curious to see what it does and what the experiment really is.” - P04. Other participants remembered that dog-like robots were like predators in movies so they would need more time to be more familiar with it. “Because I watch a lot of movies, where robots do come to life. It was walking like a dog or like a predator. So it did feel a little bit, it would take time getting used to.” - P12. One participant was cautious of the Spot platform because dog-life robots were weaponized in a TV show. “In Black Mirror, the robot is exactly like this dog. And there’s a sword that comes out of it. The sharp thing comes out of its body and it attacks you, so I was like really cautious if something is just going to pop out of it.” - P19.

Robot’s Capabilities - Appearance
To most of the participants, the HRE study was the first time they saw a Boston Dynamics Spot in real life. Without any information about the Spot platform given to them prior to the study, they were unfamiliar with the Spot platform and uncertain about what it can do or was going to do in the study. “I was like, asking myself questions about what’s gonna happen next.” - P10. Due to its dog-like appearance, some participants implicitly treated the robot as a wild animal. They seemed to expect that the robot would act like a certain animal and projected some stereotypical wild animal behaviors onto the robot. “kind of similar maybe to some other animals like a black panther, like those animals, because those animals usually have long legs and are good at running”, - P06. This projection made some participants cautious because of the possible outcomes of encountering a wild animal. “Probably because this [ robot] had limbs. That doesn’t have limbs [other delivery robots]. I know that cannot charge and cannot run like an animal behind me. But this doesn’t give me the same security.” - P07. To others, the connection between the robot and wild animals was even alarming as they thought the robot might hurt them when they got closer to it. “When it was walking towards me, it definitely looked like a dog. When it came closer, it wasn’t like fear but it was just a momentary shock. Like, what if it jumps on me?” - P12. The answers showed that the unfamiliarity with the robot and the uncertainty of its capabilities made some participants react negatively. On the other hand, participants who recognized Spot as a robot that looked like a creature were intrigued by its appearance.
“I would say the looks of it stood out to me, the way it looked modern and robot-like, and also, like a creature at the same time. So that is what intrigued me. And I found that interesting. Me being maybe more on the techie side, curious about technology, and like future technology and stuff. I'm more comfortable with it. Because I see the possibilities.” They seemed to be comfortable with Spot because they perceived Spot as a robot. This perception allowed them to associate Spot with technology and afforded them more confidence and certainty that Spot would behave like a robot. “Yeah, I mean, I was pretty confident walking by, I wasn't worried or anything like the robot or something would happen to me” - P01.

**Robot’s Capabilities - Walking**

Due to technological constraints, the Spot platform continuously stepped in a fixed rhythm when walking or turning in order to prevent falling over, producing a kind of marching gait. This was a major difference in gait compared to the relative smoothness and stillness of quadrupedal animal movements. This marching gait seemed to make participants less confident that it was safe when they were approaching the robot. “When it started walking like ‘Ta Da Ta Da’, I got a little startled. But then I had in my mind that it's going to come towards me. So I was, overall scared.” - P07. The robot’s ability to walk was frequently cited by participants in interviews. Some participants described the robot’s quadrupedal gait as unusual, particularly its mechanistic character. “I did feel like the walk, or the style of it walking was a bit mechanical. So when I first saw it coming, walking towards me, it took me a second to get used to that.” - P14. This unfamiliarity led to a feeling of surprise. “When it started moving, I was a little taken by like okay, this moves a little differently.” - P08. Some participants commented that even though they knew being near to the robot was safe, its unusual gait made them nervous simply because they were not used to it. “When it started walking, it kind of made me nervous, to be honest […] Like I knew that it was safe, but it’s not something that I’m used to.” - P15. The robot’s gait was cited multiple times as something that needed improvement, especially when participants were asked whether the robot would be suitable for deployment outside a laboratory environment. “After it walks a little bit naturally and makes less noise, then it would make sense, then it would easily blend in with the surroundings as well. Not necessar[ily that] it should look like a natural dog. But it will easily blend in” - P16. This answer implied that participants presumed most other people would be unfamiliar with quadrupedal robot gaits. There were also other participants who identified the robot’s gait as its major difference from the more familiar quadrupedal walk of a dog. “It looked to me like a dog. […] But the thing is, it was maintaining its pace, which dogs do not, generally mostly might not do. They might walk faster or slower. So I figured that it’s not a dog.” - P18. Such comments reveal both the novelty of robotic gaits and the association of quadruped robots with canines.

**Robot’s Capabilities - The Sound of Footsteps**

In the HRE study, the hardwood flooring made the robot’s footsteps loud. Several participants were initially surprised by the sound of the footsteps because they were simply louder than expected. “That thumping noise that it was making, that was also, again, because I was not expecting it to make that noise, so when it started, I was just taken aback.” - P08. The unexpected noise from the footsteps was even scary to another participant. “When I saw it, it was fine. But then it started walking it was really loud. That's the first thing I noticed. And I feel like if it was a little quieter, I wouldn't have been as nervous or scared around it.” p02. The sound was also a cue that seemed to make some participants perceive the robot as a wild animal. “I didn't know that it makes that noise that horse makes.” - P07. Despite being surprised by the sound, several participants soon realized that the reason why the footsteps were loud was because of the hardwood flooring of the hallway, and the sound might be normal had the robot walked on a cement floor. “The sound of it walking kind of struck me, but I kind of think the possible reason can be that it was a wooden floor. […] But if it is maybe a normal, cement road, or like, ground or a track, maybe it wouldn't sound that much.” - P17. The recognition of the effect of the physical environment helped the participants understand why the robot was making the sound, and the negative reaction was not as strong as others.

**Robot’s Capabilities - Camera**

Several participants noticed the cameras on top of the Spot platform. Some of them were curious about the camera’s utility. “I was asking more like technical questions about the camera and the laptop attached. I'm still curious about that. Like, was the robot able to sense that I walked up on this side of the hallway, and then it changed its path? Is that what happened?” - P02. Others were concerned about privacy issues. “If people on a street see that there’s a camera on this thing, and it’s recording them or seeing them, then they might feel like okay, this is an invasion of my privacy or something.” - P20. In general, privacy issues did not seem to be the main trigger for the participants to react negatively. Participants seemed to acknowledge that cameras were essential for autonomous robots, and our society was already full of cameras, such as smartphones and street cameras. In other words, the participants were already familiar with the idea of being exposed to cameras and that the robot’s cameras were not used to spy on them. “There will be scenarios that I might think that it is kind of recording, or it is watching or who is watching or whatever it is. But I do agree on the point that if there is a robot working, delivering stuff, I wouldn’t mind.” - P17.
Robot’s role - Purpose
During the interview, a prototypical question “What is the robot doing here” was frequently asked by the participants. This question prompted us to try to understand if knowing the robot’s purpose was important, and if there were any changes in the reactions after knowing that the robot would avoid them. Firstly, some participants were curious about what the robot was going to do. “It was the point of just passing through, and I didn’t know what was going to happen. So I was just curious about that what the interaction would be” - P04. Having little certainty about the robot’s actions was uncomfortable for some participants. “I was kind of thinking about who’s gonna make way for the other. Am I gonna crash into the robot or something? So that kind of made me feel a bit uncomfortable.” - P20. Upon reflection, participants replied that they would be less cautious had they known what the robot would do. “If I know that the robot is just to walk from that side to this side, which I already knew. And the robot might change its path to stay in its lane, then I could be a little less cautious. And also, I would say safe, because I know what it’s trying to do and what it can be, it might not do anything to me. It's just completing its work.” - P18. After knowing that the robot would change its lane and avoid the participants, some of them felt excited. “I just felt excited about seeing how it avoided me” - P05. Another participant seemed to become a lot more confident in encountering the robot. “It sensed my movement, and it changed its direction. After that, I became extremely normal. I was like, okay it's a good robot. After that, I have been completely warmed with it.” - P07. In addition, some participants also increased their familiarity with the robot and confidence in walking across it by associating it with typical pedestrians, and the robot was just tasked to do something. “I felt like it had a mission, the robot doesn’t care about me, it was tasked to move from point A to point B.” - P10. Some participants felt that it was important to know the purpose of autonomous robots because robots were developed by humans, so their actions were determined by the intentions of the developers. “Maybe it’s being controlled or it's been made, it's been programmed by humans, I would be curious to know what was the human thought process or like why did they think it's okay to let the robot out? ” - P14. Another reason why knowing robots’ purposes was important was that humans’ actions might depend on the robot’s purpose. “I feel like it's important to know, like, if it's an emergency, you can get out of his way. But if it's like running deliveries or whatever, then you don't have to be as conscious about it. As long as the purpose of the robot is always clearly stated, no one's gonna have a problem with it” - P21. This was also an indication that being more certain of robots’ purpose can have reciprocal benefits to both humans and robots. Overall, knowing what the robot would do was a resolution to many participants’ uncertainty about the encounter. “I now know that it's a robot, and what it does, like how it walks. So I was pretty much okay, knowing what this is.” - P08.

Robot’s role - Presence of Human
In the Leashed condition of the HRE study, there was a research team member walking alongside the robot with a dog leash tied to it. The presence of a human next to an autonomous quadruped robot resembled a typical human-dog dyad which increased the participants’ familiarity with encountering the robot. “I think because we're at a stage with robots, like they're so new. That seeing a person with a robot, you can recognize a person. There's this familiarity factor. Like I can recognize a person and if a person's okay with this robot, it must not be scary, or anything like that. Maybe that's why I wasn't extremely uncomfortable with it.” - P13. The higher familiarity with the human-robot dyad was also comforting to some participants. “Having a person holding the robot was very comforting” - P02. Some participants also commented that besides the familiarity factor, they can also judge if a robot was safe by assessing the human next to it. Additionally, if the robot caused something, the human could be held responsible. “I can see the human, and I can judge his intentions, and even if something is going wrong, I can hold him accountable”. - P19. Some participants commented that having a human present meant that the robot was under control, which offered some certainty and confidence that encountering the robot was safe. “Maybe more secure, that at least a human is having a hold of the robot. So if something happens, just in case, they have at least control over it.” - P17. Some participants assumed that robots would have an emergency button, and humans could shut it off if anything dangerous happens. “I will just assume that there was an off button, you can just put on the code and they'll shutdown, or you can just shut it down manually. So I didn't feel worried about that at all.” - P09. Another participant made an interesting comment that since robots do not have emotional control, then having a human controlling it will make people feel safer. “Since robots in our society are not normalized yet. I feel robots need to be controlled by humans with EQ, robots don't have EQ. So if it's going to do something dangerous to children, maybe in a park, humans need to have a button to shut it down.” - P07.

The Mental Proximity Between the Robot and the Participants
In the free-form interaction session, the robot was stationary at first and some participants felt the robot was friendlier compared to when it was walking. “When I was nearer to the robot, it was standing there quiet so that I felt like it's more friendly.” - P21. The sense of friendliness could be a result of knowing that the robot would avoid the participants and the lack of loud footsteps. Additionally, when the research team operated the robot to perform additional tricks, many of the participants felt fascinated by it and became more interested and curious about what else it can do. “I was surprised that it can lay down as well. Like, I think after the second interaction, it makes me
feel more curious and more positive on the robot because it can do a lot of tricks.” - P11. The interaction session was also an opportunity for the participants to get close to the robot and observe its machinery and technological parts. “After I took a closer look at all the components and everything, I was amazed how it was working perfectly with all the heat running through.” - P09. Many participants took the chance to interact with the robot directly, “I was like getting near it. And I wanted to see it sit and I want to take pictures of it.” - P07. The direct interaction, such as photo taking and touching, gave the participants more certainty that the robot was safe. “When I touched it, I felt more like safe with it in a way, it made it more real, I think it stops becoming something that like I can't reach or something that I shouldn't be able to touch, or like not interact with. It was more like Oh, you're here. I'm here. We're in the same space.” - P15. The increased mental proximity between the participants and the robot was a resolution to many participants' negative reactions to the robot earlier in the hallway. “During the second time, when seeing the stepping scene or how it turned or how it behaved, I don't feel that like scared.” - P05. Some participants also mentioned that they became more curious about the robot when they felt like they were closer to it. “I feel like closer to it, I was like oh, what else can you do? I want to know more about it. I think from far away, it looks scarier, like oh I don't know how big it is, or how fast can it move, but once I was like up close, I was like oh it's just a robot. I feel like I want to know more and more, like intrigued.” - P10.

In our study, only one participant (P03) stayed not surprised and not curious throughout the study. When asked why she was not surprised, she replied: “I mean, I've been around robots before, not a crazy large amount. But I've seen robots similar to that one walking or seeing pictures and media online, things like that.” This answer seemed to indicate that she was already quite familiar with the Spot platform and well-informed about its capabilities. Furthermore, when we tried to probe why she had the unsurprised reaction by asking if she knew what the robot was going to do in the experiment, she replied “I was expecting it to have some sort of reaction. But like, it did. I wasn't crazy surprised. I went Oh, okay.”. The answer seemed to imply that she believed robots were typically tasked to do something. This was evidenced by her later response: “I mean, I guess I was expecting it to do something as I walked by. Such as make sure it didn't run into me”. Similar beliefs were expressed by other participants. “The robot is supposed to be created by humans to do certain tasks.” - P15. The assumption that the robot's purpose was to support humans made P03 not surprised by the robot's actions. P03 also was the only one who decided to skip the free-form interaction session, because she felt like there were no more interesting things to see, and she disengaged herself from further interactions with the robot. “I didn't think much would change besides just me approaching it, and it would walk around like it did before.” - P03.

Opportunities Offered by the Study Protocol
Sensitizing on moments of change in reactions lets us view the HRE study as a set of opportunities for the participants to change or update their perceptions of the robot. In the HRE study, the participants had a change in reactions in two moments. The first moment was when the participants and the robot encountered each other. Passing the robot was an opportunity that gave the participants certainty that the robot would not run into them or physically harm them. In other words, the robot's action was a resolution to the participants' uncertainty about its purpose in the HRE experiment. The second moment was the free-form interaction session. This session allowed the participants to directly interact with the robot and ask any questions they might have. With direct interactions, several participants increased their mental proximity to the robot and their reactions and perceptions of the robot became more positive. The presence of humans was another opportunity that helped the participants speculate the robot's role in the HRE study. The resemblance of the human-dog dyad presented a sense of familiarity and that the robot was under control. These helped the participants gain certainty and confidence in encountering the robot. Other than the HRE study, the interview session provided opportunities for the participants to reflect on their experiences in the study. During the interview, several participants took the chance to ask questions they might still have. The answers they received helped them gain more familiarity with the robot.

DISCUSSION
Reaction, Familiarity, Certainty, and Confidence
Our emerging theory proposes that human reactions to encountering an autonomous quadruped robot in an HRE scenario are associated with familiarity, certainty, and confidence. Before the encounter in the experiment hallway, the participants were not aware of the robot’s purpose. Therefore, their reactions to the robot largely depended on their prior experience and familiarity with robots in general as well as their certainty and confidence in encountering the robot, which was influenced by their perceptions of the robot’s capabilities. In terms of the robot’s capabilities, we identified several categories, including appearance, walking, the sound of footsteps, and camera. After the encounter, participants were naturally made aware that the robot would avoid them in the hallway, hence the participants’ reactions changed to more positive. In other words, the participants gained more familiarity, certainty, or confidence in encountering the robot by having a better understanding of its purpose. In the free-form interaction session, the participants had more opportunities to directly interact with the robot. They took the chance to get close to it, touch it, or take photos of it. These opportunities increased their mental proximity with the robot and hence
gained familiarity, certainty, and confidence in it. The presence of a human next to the robot mimicked a typical human-dog dyad, which increased the participants’ familiarity with it. Additionally, the presence of a human seemed to imply that the robot was under control, therefore, it provided a sense of security, and the participants’ certainty and confidence increased, and they replied that they would feel better about it if there was a human next to it. Opportunities to increase familiarity, certainty, and confidence were keys to participants’ resolution or relief from their negative reactions and uncertainty, and lack of confidence in their ability to predict and understand the robot.

We anticipate that one may argue to replace familiarity, certainty, and confidence with trust, and we can empathize with this argument. Trust has been proven to influence human-robot interactions where appropriate trust is key to successful collaborations between humans and robots (Khavas et al., 2020). Research has also investigated how to maximize trust through the design of transparency in robot systems (Matthews et al., 2020). Our study does not adopt trust as the main influence on reactions because trust is multi-dimensional. A review and meta-analysis study of trust in HRI conducted by Hancock et al. (2021) identified six categories of trust antecedents. In addition to the complexity of trust, it is typically measured using scales (Yagoda & Gillan, 2012). We do agree that trust has the potential to explain some of the human reactions in our data. However, no participants mentioned their trust in the robot in the interview, and the complexity of defining trust prohibited us from claiming trust as the driving factor in our data.

Implications for Future Research
The lab-based HRE study protocols presented here resemble real-world HREs but are implementable in a controlled setting. Although any lab-based study will suffer from reduced ecological validity compared to in situ research, our results benefited from our protocol’s higher controllability. As HRE is still nascent, our lab-based approach helped us explore select facets of HRE phenomena. Using the Grounded Theory method, we identified familiarity, certainty, and confidence as key factors influencing participants’ reactions to the robot encounters. These can inform hypothesis generation for future work on HRE with both quadruped and other robot platform types.

These findings might also inform innovation in the development of specialized HRE survey instruments. It is likely that familiarity, certainty, and confidence are not measured by currently available HRI survey instruments such as the Godspeed Questionnaire (Bartneck et al., 2009) and the Negative Attitude Toward Robots Scale (Nomura et al., 2006). The effects of the presence of humans and robot purpose, which surfaced from the interview and our observations, are also likely not adequately measured by existing HRI survey instruments. These effects will most likely continue to play a role in how humans handle robot encounters, and future HRI research may consider mixed methodologies to encompass the social nature and usability of robot deployments (Seibt et al., 2021). Triangulating interview data with quantified survey data can equip researchers with an integrated perspective to interpret the results and better understand how humans can co-exist with robots.

We provide an exploratory but nuanced account of the sources and dynamics of participant fear during encounters with quadruped robots. Fear of robots was pervasive but not universal among our participants, in line with survey-based results of the general U.S. Population (Liang & Lee, 2017). The Spot platform’s appearance, movement, and sound were all potential sources of the experience of fear during the encounter. Media portrayal of robots being used as weapons in both fictional and journalistic coverage was also referenced by participants when discussing their fears. Our study protocol offered opportunities to help the participants increase their familiarity, certainty, and confidence in the robot, which mitigated the negative emotions and reactions of participants who utilized these opportunities. This suggests that studies of fear during robot encounters should consider utilizing opportunities to touch, be near, and ask questions about robots at some appropriate point in their experimental designs. Furthermore, our findings suggest that prolonged exposure or chances of direct interactions with robots are key to improving the quality of human-robot interactions. We join calls for more longitudinal studies of human-robot encounters (Hart et al., 2022); these are urgently needed to clarify the dynamics between participant experience and familiarity with robots in particular as autonomous mobile service robots continue to proliferate in public spaces.

A major finding in our study was that knowing the robot’s purpose mitigated participants’ negative emotions and reactions. We use this to argue that HRI research into bystanders’ perceptions of robot purpose should complement existing work on the intelligibility of robots and tasks or objectives in human-robot teaming scenarios. This is not only for the success of robot deployments but also for the underlying ethical concerns (Wirtz et al., 2018). Robot personality is also a potential research direction for HRE studies. Research on robot personality has shown that humans tend to project personality onto robots (Fussell et al., 2008) as well as recognize a robot’s personality through its designs (Chien et al., 2022). Our interview data also demonstrated that some participants projected a robot personality onto the robot, such as the “friendly” mentioned above. HRE studies using humanoid robots, service robots, or customer-facing robots may benefit from considering the effect of robot personality on their robot deployments (Whittaker et al., 2021), or examine how robot personality can influence people’s familiarity, certainty, and confidence in encountering robots.
Limitations
We identified some challenges in our study. Firstly, the social nature, complexity, and unpredictability of HRE imply that there are many factors influencing how humans perceive and react to robots. Several of the identified factors in our study are context-dependent, such as the sound of the footsteps, the presence of humans, and the free-form interaction session. Our study only examined one aspect of HRE which was encountering a quadruped robot while walking across a hallway. Additionally, our study protocol provided opportunities to resolve some of the participants’ questions or doubts. These opportunities may not be applicable to in-the-wild HRE studies, as most people may just walk past the robots without explanations provided. From our data, it is unclear how people would perceive robots if their questions were not resolved. Therefore, our findings do not entail all aspects of HRE and can only partially explain how humans react to robots when encountering them.

Secondly, our interview protocol also focused more on how the participants reacted or felt about the robot as well as how they formed their reactions and feelings. This protocol allowed us to investigate more specifically the design aspects of the Spot platform. However, this protocol did not offer the opportunity to understand how the robot can be deployed in different contexts, or how the robot can be tasked with different roles. Future research may attempt to take into account the robots’ tasks and investigate how human reactions may be influenced.

Finally, studies have shown that humans form mental models of robots based on their appearance (Fink, 2012). The Uncanny Valley theory (Mori, 1970) describes the effect of the consistency between robots’ appearance and behaviors. The theory has also been validated by numerous studies (Ciechanowski et al., 2019; Kim et al., 2019). Since our study focused on a relatively advanced quadruped robot, our findings may not reflect how humans react to other types of robots. Therefore, future research should adapt our findings if using different types of robots. Additionally, one aspect of our study protocol presented a human-robot dyad that resembled a human-dog dyad. This resemblance increased some participants’ familiarity with the robot and mitigated some of their concerns. However, this might have contradicted the idea of robots being autonomous. As commented by one of the participants, having a human next to a robot might not always be ideal. “It wouldn't make sense because the robot is supposed to be created by humans to do certain tasks. And if a human has to be present all the time, it doesn't make sense, right? So if the robot should be autonomous, it should be able to do everything on its own.” - P12. More research is needed to investigate the presence of humans next to autonomous robots.

CONCLUSION
The development of autonomous quadruped robots allows organizations and businesses to deploy robots to facilitate business operations. The deployment of robots will generate multiple human-robot encounters. However, how humans handle robot encounters in everyday life environments is still understudied. This work fills this gap by adopting participatory observation in a lab-based HRE study and applying Grounded Theory methodologies for data collection and analysis. The novel study protocol allowed us to explore human reactions to an autonomous quadruped robot, Boston Dynamics Spot, in a lab-based scenario that preserved the relevant aspects of real-world encounters. Our major contribution is an emerging theory that explains the relationship between human reactions, familiarity, certainty, and confidence in encountering an autonomous quadruped robot.

Encountering an autonomous quadruped robot such as the Spot platform was still an unusual experience for most participants. When they first saw the robot in the HRE study, they relied on their prior experience to speculate about the robot’s capabilities for judgments. With one exception, participants’ first impressions were some combination of curious, surprised, cautious, or scared. After the encounter, participants had a better understanding of the robot’s purpose in the HRE study, and hence some of their doubts or questions were answered. In the free-form interaction session, the participants had a chance to directly interact with the robot. Those who did so reported that this opportunity helped them realize that the robot was safe and was something they could touch or use. As a result, their mental proximity to the robot increased. The encounter and the interaction session were two opportunities offered by our study protocol to resolve the participants’ unfamiliarity, uncertainty, and lack of confidence in encountering. We suggest other HRE studies consider adding such opportunities as appropriate for their research goals.

This work can serve as the theoretical basis for future research in mobile autonomous service robot design and deployment. Our emerging theory that reactions are associated with familiarity, certainty, and confidence sheds light on the dynamic and experiential characteristics of HRE. Future studies can adapt these findings and our emerging theory to generate, develop, and refine hypotheses, and revise or develop specialized HRE survey instruments.

ACKNOWLEDGEMENTS

Engaging Participants in Online Interviews: Lessons Learned from Implementing a Participatory Visual Approach in Two Explorative Health Information Behavior Studies

Dewitz, Leyla

Berlin School of Library and Information Science, Humboldt-Universität zu Berlin, Germany | leyla.dewitz@hu-berlin.de

ABSTRACT
This article provides a theoretical background on participatory approaches in (health) information behavior studies. Furthermore, it introduces and discusses the implementation of a visual participatory approach applied in two explorative health information behavior studies, each conducted online via Zoom and with the virtual whiteboard Miro. One study examined the health information behavior and digital well-being of individuals with social anxiety ($n=22$), while the other explored health information behavior in the context of false information and scientificity ($n=21$). The approach aimed to actively engage participants within the interview setting through creative and visual elaboration and representation of health information interactions using the virtual whiteboard Miro. Findings show that using visual materials during face-to-face interviews facilitated the communication about sensitive health content and supported to capture key statements in situ, promoting the externalization of tacit knowledge during the interviews. Despite the content differences of the two studies, the unifying aspect examined in this article is how the implementation of the visual participatory approaches could enhance interview settings and lead to gathering rich data. This article fills a gap for methodological considerations of participatory techniques within (health) information behavior studies.

KEYWORDS
Health Information Behavior, participatory research, qualitative methods

INTRODUCTION
Qualitative methods can provide a deeper understanding of human behavior and thus can be used to interpret human practices in a variety of contexts, including people's (health) information behaviors (Lambert & Loiselle, 2007; Bates, 2004). Health information behavior studies – and in particular qualitative, in-person interviews – pose potential difficulties for both the participant and researcher. The researcher’s challenge is to create and establish a setting within a question-and-answer situation that enables participants to freely disclose sensitive and highly personal information to the unfamiliar researcher, who generally does not disclose sensitive content about themselves (Clarke, 2006). In order to enhance the interview setting in regard to trust and rapport between the participant and the researcher, the use of participatory methods can be a valuable approach. This article aims to contribute to the field of health information behavior by presenting participatory methods as an approach to engage participants within research by moving beyond researching participants to conducting research collaboratively with them. Participatory approaches focus on individuals’ lived experiences, including their thoughts and emotions, social perceptions, behaviors, and interactions. Participatory studies emphasize collaboration and (co-)creation of knowledge between participants and researchers by recognizing that individuals and communities have unique and relevant experiences and perspectives (Meyer et al., 2020). By involving participants in the research process, researchers can gain a more nuanced and context-specific understanding of the issues studied. Critics of such participation state that it can sometimes be used superficially, without truly engaging study participants. For example, Hart (1992, 2008) has offered valuable assessments of the various stages of participation (see ladder of participation), including tokenism. There are many perspectives on what participatory research is or could be (see Northway, 2010), but one of its key contributions is summarized clearly by Cornwall & Jewkes (1995): “the key difference between participatory and conventional methodologies lies in the location of power in the research process” (p.1667). In other words, participatory research responds to conventional attitudes towards – and raises ethical questions about – the role of the researcher, attempting to overcome such conventional power dynamics to whatever extent possible by encouraging researchers to stand back and give a voice to participants, who are de facto experts on their own knowledge. Whereas participatory research is seen as an approach to addressing power dynamics in the research process, it is important to state that such dynamics may persist in participatory research despite efforts to create equal partnerships between researchers and participants. For example, researchers may still hold more power in decision-making and in analyzing and interpreting data (Wallerstein et al., 2019).

This article presents both a theoretical framework and a practical proposal for incorporating participatory approaches into qualitative interviews, in order to contribute to the wider discussion of methodological variety in qualitative information behavior research. It provides an overview of the state of the art regarding participatory methods.
interview formats, focusing on (health) information behavior research. Two hands-on examples serve as case studies to show how, on the one hand, visual participatory approaches can be used within or adapted to interview studies. On the other hand, these examples are intended to clarify when visual participatory approaches could be appropriate or helpful within interviews and which specific challenges they could counteract or entail. Towards those two aims, this study introduces these visual participatory approaches within the two case studies by describing the procedure, the implementation, and the lessons learned by applying them. The first study examined the health information behavior and digital well-being of individuals with social anxiety (n=22). The second explored the health information behavior and perception of scientificity in the context of false information among adults (n=21). Both interview guides consisted of various visual participatory elements created in the virtual whiteboard Miro. The visual elements were also intended to help visualize the verbal interaction through and facilitate the interactive discussion of visual materials.

The structure of this article is designed to provide a comprehensive overview of participatory approaches within health information behavior studies. The literature review serves as an introduction to (health) information behavior and participatory research, providing a frame of reference for the key aspects of the subject matter. This section also includes examples of previous (health) information behavior studies that have employed participatory methods within their research design. The method section presents a more detailed account of such approaches by elaborating the study design of the two health information behavior studies described in this article, employing a digital visual approach. The discussion explores the theoretical considerations that were incorporated into these studies and how they align with the examples presented in the literature review. The following section highlights the lessons learned from these two case studies, presenting key considerations for and benefits of participatory approaches. Finally, the last section summarizes the findings, providing an overall conclusion.

**LITERATURE REVIEW**

**Health information behavior**

Information behavior in general characterizes the multitude and complexity of how humans engage with and respond to information (Greifeneder & Schlebbe, 2023). It captures information interactions in relation to sources and channels, including active as well as passive information seeking and use (Wilson, 2022; Bates, 2017). To study this provides a basis to gain knowledge on how to enhance information access in a rapidly changing information landscape (Spink & Cole, 2006). (Health) information behavior research draws on multiple theories, models, and methods to understand the complex and dynamic ways in which people interact with information (Johnson & Case, 2012). It refers to the various ways in which people seek, acquire, share, evaluate, experience, use, or even avoid health information (Lambert & Loiselle, 2007; Dewitz, 2022). Accordingly, it includes both active and passive behaviors (Kelly et al., 2014) and is sometimes associated with the need to make life decisions based on health information (Soroya et al., 2021). The acquisition of health information sources and practices can be both interpersonal and institutional: people search for information online, seek advice from friends and family and peers, consult health care providers (Smith, 2014), and use various new and old media to obtain health information (Riaz et al., 2021). These behaviors can be influenced by a variety of factors, including personal (e.g., personal characteristics, health status, education and health information literacy, socioeconomic circumstances), context (e.g., cultural and social norms) and device-specific (e.g., access or lack of access to technology and technology modalities) (Dewitz, 2022). Besides the many examples of quantitative approaches in interdisciplinary health information behavior research (for an overview see Gilbert et al., 2021), a broad variety of studies also apply qualitative methods when focusing on health information behavior (Oh et al., 2016; Lambert & Loiselle, 2007).

Interviews are widely used and effective at revealing a deeper understanding of everyday information interactions (see Bates, 2004) and for in-depth examinations of various health information behaviors (Greyson & Johnson, 2016). Qualitative health information behavior studies focus on (vulnerable) social groups with specific health needs, such as LGBTQI+ individuals (e.g., Kitzie et al., 2020), the elderly (e.g., Huisman et al., 2020), (young) parents (e.g., Greyson, 2017), people affected by cancer or other chronic or physical illnesses (e.g., Bressel, 2022; Costello, 2016), and people with a psychological disorder (e.g., Aref-Adib et al., 2016). In times of the Covid-19 pandemic, health information behavior studies also shed light on multiple health information interactions of laypeople (e.g., Soroya et al., 2021), changes in (health) information behavior (see Montesi (2021) for a comprehensive overview) and false information regarding health (Savolainen, 2022).

**Participatory research**

Participatory research is an approach that actively engages study participants or the community throughout all stages of the research process, ranging from jointly designing a study to reporting and sharing the results (Northway, 2010). It is rooted in emancipatory beliefs and values and takes the approach of conducting research with participants rather than on them (French & Swain, 2004). It often adopts a critical stance toward society by giving voice to marginalized and vulnerable groups in particular and advocating for applied research, solving problems through research while seeking to reshape conventional research practices, power dynamics, and the generation and...
use of knowledge (Cornwall & Jewkes, 1995). For a general overview on participatory research frameworks, orientations, and examples of study approaches, see Vaughn & Jacquez (2020). Participatory interview methods actively involve participants in the research process, giving them a greater degree of control and influence over research questions, methods, and outcomes (Salmon, 2007). Building rapport with participants is an important part of the qualitative interview process, especially in participatory research (Atkinson, 2005).

One way to lighten up a question-and-answer situation in an interview is to use participatory or creative methods, for example jointly producing visual artifacts (Wilkerson et al., 2014). According to Rainford (2020), such creative elements can yield positive outcomes by promoting reflexivity and facilitating more engaging discussions. Moreover, these methods allow for a more nuanced exploration of complex issues, moving beyond simplistic binary thinking, given that visual artifacts can unlock less linear, more free-flowing thinking that is not necessarily constrained by speech. In fact, creative exploration during an interview can serve as a valuable starting point for developing thoughts about personal experiences (Gauntlett & Holzwarth, 2006; Literat, 2013). Several participatory studies have employed art-based methods or other visualization techniques as a means of facilitating engagement and interaction within interview settings (e.g., Hwang et al., 2022). By using methods that involve creating visual representations rather than solely relying on verbal communication, researchers can gain deeper insights into the practices and behaviors of participants (Bagnoli, 2009). This shifts the dynamic of the interview from a static question-and-answer situation to a creative activity of making or producing something together and discussing it (Gauntlett & Holzwarth, 2006). In addition, the implementation of entire participatory design formats in HCI health research has demonstrated effectiveness in facilitating the externalization of tacit knowledge, opinions, backgrounds, and needs (Langley et al., 2018), particularly in sensitive subject areas like mental health (Flechtner et al., 2023). In the latter years of the Covid 19 pandemic, digital tools were used to conduct or implement interviews. For example, the digital whiteboard Miro became frequently used within online interviews or design workshops to enhance brainstorming, ideation, and mapping – ensuring creative and flexible engagement through visual elements (Slingerland et al., 2022; Cerna & Müller, 2021; Wong-Villacres et al., 2020). Creative methods used in physical in-person interviews can thus be transferred into a digital format. Miro’s most basic form enables the use of virtual sticky note notes, embedding videos, pinning documents or presentations to the board, inserting illustrations or images, adding drawings, and attaching annotations and comments, making it possible to tailor the units to the specific needs of the study design and use them in real time.

(Health) information behavior studies and participatory approaches

Participatory approaches are gaining popularity in the field of health research (Abma et al., 2019; Cargo & Mercer, 2008). However, in the information science domain of health information behavior research, only a limited number of studies have employed participatory approaches (e.g. Genius, 2010; Freund et al., 2016; Greyson et al., 2017, Greyson, 2013). Therefore, this section presents both information behavior studies and health information behavior studies using participatory approaches.

The series of methods, tools, techniques, and theories constituting participatory approaches can be applied to information behavior studies (see Meyer et al., 2020 for a comprehensive scoping review on participatory design and information behavior). Already there is a growing body of literature in information behavior research employing participatory elements in interviews (Sonnewald et al., 2001; Hartel, 2014; Dewitz, 2021a,b; Schlebbe, 2022; Greyson et al., 2017; Greyson, 2013; Meyers et al., 2007; Barriage, 2021). Several qualitative studies in information behavior research have adopted participatory approaches as a means to promote active conversation (e.g., Dewitz, 2021a; Given et al., 2011). These studies have focused particularly on groups considered vulnerable, including refugees (e.g., Fisher et al., 2016; Dewitz, 2021a, b), children (e.g., Schlebbe, 2022), and adolescents (e.g., Meyers et al., 2007). It is possible that individuals from certain social groups may find it difficult to share their experiences and needs with others due to the sensitive nature of the content. Therefore, participatory approaches could help to facilitate communication and self-expression and allow participants to convey complex emotions and experiences otherwise difficult to express using traditional interview methods alone (Dewitz & Schlebbe, 2022). Additionally, individuals belonging to vulnerable groups may face barriers in accessing or recalling past experiences for various reasons (Dewitz, 2021a). It is important to note that if these experiences involve sensitive content, conducting studies using participatory methods without the guidance and approval of psychologists or an ethical board is not recommended (Flechtner et al., 2023). Information behavior research in general has emphasized the effectiveness of participatory approaches in exploring participants' experiences, needs, and other behavioral interactions with information. This involves moving away from traditional research practices that solely focus on studying participants, towards conducting research with them instead (Meyers et al., 2007). By prioritizing opportunities for participants to express their opinions, accommodating diverse abilities and interests, allowing for participant choice, and covering different communication styles (from visuals to vocal), researchers can enhance their knowledge of how people interact with information to gain a richer and more nuanced understanding of participants' experiences (Barriage, 2021; Greyson et al., 2017, Greyson, 2013). In a study conducted by Barriage (2021), the information
practices and experiences of 5-to-7-year-old children were examined. The study investigated the information needs and activities of young children, as well as the challenges they faced, the support they received, and the emotions they felt while engaging with information. The study employed a participatory approach in different stages. One stage involved a book discussion, while another stage involved uploading pictures of everyday live interactions using the PixStori app. Another stage involved a conversation about the photos taken. Schlebbe (2022) used a participatory element as part of the mosaic approach to encourage children to visualize their "dream tablet" by asking them to draw wishes of what they would like to do with their tablet to gain a deeper understanding of the participants' information wants regarding mobile technology. Greyson et al. (2017) used a participatory, arts-based method in an interview study with young parents aged 15–24 years to gain deeper insights into (health) information practices. The study shows an innovative and interactive drawing-based interview technique, which can be easily adapted within qualitative interviews, guiding participants in depicting their personal social information worlds. A few questions helped participants draw their information worlds, for example illustrating how and where they looked for information when they had a health problem. For Greyson et al. (2017), such visual and creative methods have great potential to enhance research into everyday information practices and the information behavior of marginalized groups in particular. In another study, with refugee adolescents, regarding information behavior and smartphone use before, during, and after their flight to Germany, Dewitz (2021a,b) used maps in physical face-to-face interviews and app icon cards that the participants adjusted to a world map (flight route). This interactive participative interview element served as a low-threshold and a playful way to lighten up the static question-answer structure, actively engaging the participants in an age-appropriate manner. This corresponds with Agosto & Hughes-Hassell’s (2006) claim that participants are eager to participate in research that permits them to express their ideas and opinions.

Overall, these studies suggest that incorporating participatory elements into (health) information behavior studies can enhance the quality and richness of the data obtained and can help to promote a greater degree of engagement and empowerment among participants. However, it is important to carefully consider the ethical and practical implications of using participatory methods and to ensure that participants are adequately informed about their rights and supported throughout the research process.

METHOD
This paper presents (digital) visual participatory elements that can be adapted to (health) information behavior interview studies to gain a deeper understanding of participants' interactions with health information and to actively involve the participants in the research. Methodologically, the article is based on an extensive literature review of the central aspects of participatory approaches generally and in regard to (health) information behavior studies. It further presents two practical examples of exploratory interview studies in which (digital) visual participatory elements were employed. Central aspects between the theoretical and the practical part of the article are further compared and discussed. This article aims to methodologically introduce a visual participatory research approach for health information behavior studies that can be employed within qualitative (online) interviews to engage participants actively in the research process.

Research design of the two health information behavior studies
Despite the clear benefits of interactive participatory elements in (health) information behavior studies, researchers must consider the sensitivities and challenges involved in applying them. For this reason, this section presents a visual approach to participatory research in order to exemplify how to engage participants in (health) information behavior studies.

Two studies using hands-on examples were (co-)conducted by the author using visual participatory elements within two qualitative interviews. One study (I) examined the health information behavior and digital well-being of individuals with social anxiety (n=22), while the other study (II) explored adults’ health information behavior and perception on scientificity in the context of false information (n=21). The interviews were conducted online via the video conferencing platform Zoom. Both studies are based on qualitative research approaches (study I: thematic analysis; study II: grounded theory) and therefore involve semi-structured in-depth interview guides as their data collection method. Because both studies will soon be published, a methodological analysis based on the empirical material is not presented here. Therefore, the following sections will rather describe the design and implementation of the visual participatory approaches of the two studies using the virtual whiteboard Miro. This aims at summarizing the potential of visual participatory elements within qualitative online interviews and elaborate on the benefits and challenges that such approaches entail.

The visual participatory approach was implemented to introduce a low-threshold and playful way to diversify and introduce more lightheartedness to the otherwise static question-answer structure and introduce greater interaction between participants and the researcher. In addition, it was intended to motivate the participants to articulate their needs, experiences, and ideas and to stimulate their memories, making it easier for them to remember past
experiences and to draw on explicit and tacit knowledge. Using visual approaches to discuss abstract concepts such as 'health information behavior' and 'digital well-being' helps to simplify and convey them in accessible and comprehensible language. This is essential for facilitating discussions about these topics, which participants encounter in their daily lives but may not have explicitly considered before. This approach allows for the avoidance of potentially confusing terminology and instead translates these concepts into relatable actions and visual representations, promoting the construction of bridges of knowledge.

As these two hands-on examples show only a simple form of a participatory approach, it is important to note that participatory research as a whole is and can be much more than the inclusion of visual interactive-participative elements within interview studies. The case studies represented here are an initial attempt to approach participative research as a whole is and can be much more than the inclusion of visual interactive-participative elements within interview studies. The case studies represented here are an initial attempt to approach participative methods and will be further developed by the author.

Miro as tool for data collection in both studies
In both studies, the digital whiteboard Miro – which enables the visualization of specific interactions and material – was used to implement the visual interactive elements. For both studies, a clear design was chosen within the elements in order not to overwhelm or distract participants (see Figures 1 to 5). The Miro boards were devised by delineating specific areas for user input. In both studies, the researcher elected to manage the Miro board and received guidance from the participants. This approach avoided overwhelming participants with digital methods or forced activity. The researcher shared the screen on Zoom and was responsible for incorporating the participants' inputs into the Miro board. Miro was chosen due to its versatility and ability to easily adapt to the purpose of both studies. It was particularly useful for visualizing various contexts of interaction with technology and mapping personal health information infrastructures, as well as for classifying different images or app use. The Miro board was set up to allow participants to select relevant elements related to each task and move them into place with the researcher’s help. Participants were encouraged to verbally express how the researcher should navigate, for example, the app icons and rating buttons (see Figures 1, 2, 5).

Study I: Health information behavior and digital well-being of people with social anxiety
Study design
The study examined the health information behavior and digital well-being of individuals with social anxiety (n=22). Miro was used during the online interviews to collect and map the apps frequently used by participants, which were subsequently evaluated by participants in terms of how they impact their subjective (digital) well-being. A second Miro board was introduced to allow the participants to visualize their (mental) health information infrastructure (inspired by concepts such as information horizons and information worlds), for example by gathering and bringing in connection health information sources and health information needs. All interviews sought to understand the relationship between the digital well-being and health information behavior of people affected by social anxiety disorder (SAD). For this reason, a method was sought that would encourage participants to open up about their technology use, habits, and behavioral interactions in relation to health information.

Participants and sample
Two pretests were conducted, first with a psychologist to sensitize the researcher and to evaluate the feasibility of the interview guideline and the visual interactive elements from a psychological and ethical perspective. The second pretest was conducted with a person affected by social anxiety to provide the researcher with feedback on the question design, the feasibility of the interactive elements and any noticeable mental load felt during the interview. Feedback from both pretests was incorporated, which primarily included formulating the tasks more precisely for clarity. The study included 22 participants suffering from SAD, consisting of 15 women and 7 men (self-reported gender), aged between 18 and 65. All participants were informed about their rights prior to the interview and signed an informed consent form according to GDPR standards. After the interview, participants in study I were asked if they would be interested in reusing their created Miro boards themselves. Some participants later made use of them either to discuss the content with their psychotherapists or for personal use.

Challenge in this research and why it is a chance to adopt a participatory approach
SAD is characterized by an excessive fear of negative evaluation and scrutiny by others in social situations, which often results in severe stress and avoidance of social situations altogether. This presents a challenge for conducting (online) interviews with individuals suffering from SAD, as they may have high inhibition thresholds for social interactions. Participatory approaches can be appropriate for such needs because they introduce a more equal power dynamic and provide more flexibility in the involvement of participants, adapting conditions to reduce the social pressures on individuals such as those with SAD. In addition, a visual participatory approach supports individuals in expressing thoughts through nonverbal interactions, perhaps more easily than when they are in the focus of a conventional face-to-face interview.
Study procedure – the visual participatory elements within the interview

A semi-structured interview guideline was used to provide questions that were comparable across all participants but also able to respond flexibly to the needs and specific content, as well as to the interview flow. The questions within the semi-structured interview guide covered various topics, including personal information, the use of different technologies (such as smartphones and tablets), and the assessment of how and in which situations the use of technology benefited or negatively affected everyday life regarding health and digital well-being. It was important to find a way for participants to open up about their technology use, reflect on it, and draw on tacit and implicit knowledge about their behaviors. For example, a method that allows them to articulate feelings and remember situations in the past, such as a time when they had used communication technology during an instance of social anxiety. The three visual participatory elements consisted of the following three aspects: (1) identifying apps used by participants (Figure 1); (2) assessing the apps in terms of how they make participants feel (“makes me feel good”, “makes me feel partly good/not good,” or “makes me feel bad”); and (3) conducting a personal (mental) health information infrastructure, covering used sources and needs, as well as potential relationships between these two. All Miro boards were prepared using moving elements (e.g., app icons, blank cards, and sticky notes) and constant elements (e.g., the app collection [figure 1] or potential information sources / channels [figure 3]). The constant elements were implemented to provide participants with a memory aid or a useful starting point for their own ideas and impulses.

Figure 1. Miro board 1 with (from left to right) blank sticky notes, app collection, smartphone/tablet for assigning the apps used, trash can for the apps implemented but not used.

After an introduction to the interview and various questions regarding the use of technology and devices, the first Miro board was presented to the participants through screen sharing in Zoom. In the first task (Fig. 1), participants were asked to fill the smartphone or tablet with apps they use in their everyday lives. Participants were encouraged to instruct the researcher to adjust the smartphone or tablet. Apps that had not been used for a long time were assigned to the trash can. The blank sticky notes (figure 1, left) were used to add apps that had not been included in the app collection.

Figure 2. In Miro board 2 participants were encouraged to specify or classify feelings associated with the specific apps used by having them allocate those apps into categories (from left to right: "makes me feel good", "makes me feel partly good/not good", "makes me feel bad").

The next step was to assign the apps to learn more about interactions, situations or contexts, and associated feelings or emotions related to the specific apps or app use. The challenge of having to choose one of these categories (“makes me feel good”, “makes me feel partly good/not good”, “makes me feel bad”) stimulated conversation and reflection. The participants were encouraged to speak their thoughts aloud and explain why the categorization had been made. Furthermore, this interactive element encouraged participants to engage actively and deepen the conversation by motivating them to reflect on their behavior and interactions to discuss actual experiences related to
their subjective digital well-being. The overall aim of this interactive element was not to force the participants to classify the icons accurately, but to stimulate or provoke engagement with the topic of feelings and app use through exposure.

Figure 3. In Miro board 3 participants were encouraged to share information needs (questions) and information sources / channels that they have used in the past or use in present.

Miro board 3 aimed to assist participants in visually mapping information sources and channels that they had used or were currently using for (mental) health questions. In this way, information needs could be identified by gathering questions that participants had asked or were asking in relation to their (mental) health. Both aspects of information interaction (used information sources and information needs) were interwoven and compiled simultaneously to allocate relationships to the specific entities. It was important that the researcher introduced targeted questions to sustain the conversation. Ultimately, connections could be identified and drawn between sources and needs, and thus a personal (mental) health information infrastructure emerged (see supplementary material, figure 6, under the following link: https://doi.org/10.5281/zenodo.8124360).

Study II: Health information behavior towards false information and perception of scientificity

Study design
The second study investigated the health information behavior and the perception of scientificity in the context of false information among adult individuals living in Germany (n=21). Miro was used as a tool to help visualize participants' health information infrastructure and to evaluate the scientific appearance of specific resources in situ during the online interview, such as screenshots of different (scientific) health information sources.

Participants and sample
A pretest was conducted with four individuals to evaluate the feasibility of the interview guideline and the visual interactive approach within the interview. After the pretests, minor adjustments were made regarding the question design. The focus of the pretest was to find out whether the research design encouraged participants to talk about actual experiences with false information, which was positively confirmed by the pretests. The study included 21 participants, consisting of 12 women and 8 men, aged between 20 and 75. Recruitment criteria merely consisted of residence in Germany and being of age. All participants were informed about their rights prior to the interview and signed an informed consent form according to GDPR standards.

Challenge in this research and why it is a chance to adopt a participatory approach
Regarding recruitment criteria, no participants with vulnerabilities were sought specifically, although it is possible that selected participants did present vulnerabilities such as chronic illnesses. To anticipate such sensitive health topics emerging during a health information behavior study, the researcher, the setting, the interview guide, and the participatory approach in general had to be aligned to this. Moreover, false information is a delicate, controversial topic involving social judgments. Such a serious topic therefore benefited from visual participatory elements in the interview to make it more easily accessible and discussable. Inquiring about participants' information behavior regarding health, including potentially inaccurate or false information could have prompted participants to provide socially desirable responses. To mitigate such potential biases and increase the ease of communication during the interview, the integration of participatory visual elements within the interviews facilitated a natural and comfortable sharing of opinions.

Study procedure – the visual participatory elements within the interview
A semi-structured interview guideline was used in the study to ask questions that were comparable across all participants but also able to respond flexibly to their needs and specific content as well as to the interview flow. The questions within the semi-structured interview guide covered various topics, including personal information, the role of health in everyday life, and experiences with and reactions to received (potentially) false information. It was important to find a way for the participants to open up about their personal health information interactions and habits, reflect on them, and draw on explicit and tacit knowledge about themselves and others: articulating feelings and remembering situations in the past, such as those in which they came in contact with (potentially) false health information. The two visual participatory interview elements were as follows: (1) conducting a personal health information infrastructure covering used sources and needs, with a subsequent question of whether participants had
ever received false information from any of these actors or sources and (2) assessing the scientificity of different health information sources by assigning colored buttons (“scientific”, “not scientific,” or “partly scientific”) to stimulate discussion about the scientificity of health information resources and criteria for the subjective assessment of scientificity. All Miro boards were prepared using moving elements (e.g., source/actor elements [figure 4], sticky notes, and evaluation buttons [figure 4, 5]) and constant elements (e.g., screenshots from scientific/non-scientific health sources [figure 5]). The constant elements were to serve as memory aids for the participants and as a good starting point to share knowledge, helping to visually guide participants to deepen the conversation through reflection. The aim of the study was to learn more about which sources or actors participants used to inform themselves about health topics (figure 5). Since these sources of information can potentially spread false information, Miro board 4 was used to introduce and lead the topic in regards to receiving false information from any kind of actor. In order to identify used sources and actors, as well as related situations and their potential connection to each other, it was necessary to visualize this complex content to help participants remember situations and experiences and also to reflect situations during the mapping process. The Miro board was coordinated by the researcher in order not to cause additional stress to the participants. During the process, the researcher asked questions to accompany the mapping process and to maintain the conversation.

Figure 4. Miro board 4 aimed to map participants’ personal health information infrastructures with potential sources to choose from (in gray) and blank cards (sticky notes) to add sources used (left). The red rings (left) helped to mark the main sources and arrows (not shown here) to visualize relationships between sources/actors.

A second Miro board was introduced to determine how participants assess the scientificity of a health source, by showing various screenshots of scientific/not scientific health information sources. The aim was to gain deeper insights into participants’ thought processes, feelings, and ambiguities or uncertainties when assessing different health sources for scientificity. Accordingly, different examples — ranging from YouTube videos to a scientific article, book cover, or advertisement — were presented to participants via Miro and served as a basis for discussion (figure 5). The various screenshots were viewed individually for clearer focus and easier reading of texts and descriptions of screenshots. The participants were asked to adjust differently colored buttons ("scientific" in pink, “non-scientific” in blue, and “partially scientific” in orange tones) to each image and elaborate on why that source was perceived as scientific or not. Rating the screenshots was not intended primarily to evaluate the scientificity of the health information actor/source as a test of participants’ knowledge, but rather to encourage discussion and engage participants in sharing beliefs, in situ, about which attributes resources required to be perceived as scientific. The Miro board was coordinated by the researcher in order not to cause participants additional stress. At the end of the task, the view was expanded to all screenshots, and participants were asked if they were satisfied with the decision or whether they would like to add or change anything.

Figure 5. Miro board 5 was used for assessing the scientificity of different health information sources by assigning colored buttons (“scientific”, “not scientific,” or “partly scientific”) to stimulate discussion about scientificity of health information resources and criteria for the subjective assessment of scientificity.
**Overall Methodological considerations for both studies**

Though they were inspired by approaches within participatory studies – especially with regard to visual participatory elements within interviews (e.g., Dewitz, 2021a,b; Sonnewald et al., 2001; Greyson et al., 2017) – the individual elements in the (co-)conducted studies were freely developed according to the research questions (see supplementary material, table 1, under the following link: https://doi.org/10.5281/zenodo.8124360) and tested on multiple pretests to ensure that the methodological considerations were applicable. All visual participatory elements were introduced to enrich the interviews in various ways. The first was to improve the interview setting in terms of the relationship between the researcher and the participant by trying to shift the “expert function” to the participants by letting the researcher only locate what is instructed by the participant (e.g., subjective app evaluation regarding perceived well-being in technology interaction). This also avoided overwhelming the participants with potentially unfamiliar digital tools or making them feel observed or tested. In addition, a research design was sought that offered the possibility of loosening up the interview situation from static question-answer to a dynamic narrative flow. In both studies, the participatory method elicited personal health information infrastructures by identifying information sources and related information needs in a playful manner. A second way the visual participatory approach enriched the interviews was by externalizing knowledge with visual starting points for introducing conversations about sensitive topics, and further deepening those conversations. The overall methodological considerations for both studies aimed to encourage participants to recall and vocalize their thoughts by visualizing, making, or developing something collaboratively. These simple methods guided participants’ creative impulses to elaborate and acquire explicit but also tacit and hidden knowledge, through visual impressions that made knowledge more communicable, explainable, or even accessible for the participants. The aim was to build memory bridges from explicit knowledge to tacit knowledge about the participants themselves, about behavior or interactions, and about knowledge gained through in-situ reflection in the interview. One methodological challenge was not to overwhelm participants. Although the visual elements were a bridge to start conversations, there was a risk of participants perceiving them as tasks to test knowledge (figure 5). Accordingly, visual participative elements needed to be well planned, pretested, and introduced accessibly and precisely. Further, it is essential to be transparent about the research process e.g. the goal of tasks presented. For more information, access the supplementary material, table 1, (https://doi.org/10.5281/zenodo.8124360) in which the specific study designs, methodological requirements, and implementation considerations for the visual participatory elements in both studies are documented.

**DISCUSSION**

For establishing an ethically appropriate setting in interviews that enables participants to freely disclose and reveal highly personal and sensitive health information methodological considerations play a key role (Clarke, 2006). As both studies involved ethically sensitive subject matter, it was necessary to employ a methodologically appropriate procedure. Participatory approaches put the needs and perceptions of participants first, gathering data with rather than on them (French & Swain, 2004), acknowledging that individuals have unique experiences and perspectives (Meyer et al., 2020). In addition, participatory approaches focus on individuals’ lived experiences, including their thoughts and emotions, social perceptions, behaviors, and interactions (Meyer et al., 2020), which aligns with the foci of (health) information behavior research (e.g., Lambert & Loiselle, 2007; Johnson & Case, 2012; Meyers et al., 2007). Therefore, adapting a participatory approach was seen as a research-enhancing method to adapt in the presented studies. Both studies aimed to implement a low-threshold participatory approach for a more nuanced and context-specific understanding of participants’ views and experiences regarding health information. This required reflecting on every step of each participatory element to adjust it appropriately, for example in pretests with a psychotherapist (study I). As the conducted studies presented only simple participatory approaches, it is debatable whether or not the visual participatory elements are truly participatory research according to the standards set by Hart (1992, 2008) and Northway (2010). According to Cornwall & Jewkes (1995), research becomes truly participatory when power is reallocated. Accordingly, the studies conducted for this article aimed to give voice to participants as experts of their own knowledge and to give the researcher a more observing role. While the power dynamics could not be entirely reversed here, an attempt was made to address the most predominant of them. Nevertheless, the extent to which these studies were participatory was limited by not having involved participants in each step of the research design, (research questions, methods, and outcomes) which would have satisfied these after Salmon (2007). It also lacked the possibility, emphasized by Cornwall & Jewkes (1995), of identifying and solving problems in applied and subsequent practices. In addition, besides the visual participatory approaches presented here, no further attempts were made to build rapport between the researcher and the participants to the extent recommended for participatory research by Atkinson (2005). It was possible to create a trusting environment in which the participants opened up about their everyday life and lived experiences. However, the fact that the visual results in the Miro boards were made available to the participants from study I for further work can be seen as a benefit. According to Rainford (2020), Wilkerson et al., (2014) and Greyson et al. (2017), creative methods and visual participatory approaches effectively lighten up the question-answer situation and facilitate engagement and interaction within interview settings. They also shift the paradigm from a static question-answer structure to a more
creative activity of making or developing something jointly together (Flechtner et al., 2023). According to Dewitz (2021a, b), interactive practices – such as mapping or adjusting commonly used apps – provide a low-threshold starting point to identify information interactions and app use. This served as a basis to implement a certain approach in the study about health information and digital well-being of people suffering with SAD (figure 1), as it promoted reflexivity and facilitated discussion. In addition, the process of mapping and visualizing health information infrastructures – including sources and actors, needs, and situations of information exchange or sharing – opened a way, according to Rainford (2020), to a more nuanced exploration of complex issues. The visualizations of health information infrastructures in both studies helped to move beyond binary thinking to find a way of externalizing tacit knowledge (figures 2, 5), opinions (e.g., in the evaluation tasks of both studies [figures 2, 5]), backgrounds (figures 2), and needs (figures 2, 3, 4), which Gauntlett & Holzwarth (2006) and Flechtner et al. (2023) stated. In addition, as in Dewitz (2021a), the visualizations accompanying the interview process encouraged participants to convey complex emotions, experiences, and opinions, which is a crucial aspect of participatory approaches according to Agosto & Hughes-Hassell (2006). As in Greyson (2013), Greyson et al. (2017) and Dewitz (2021a, 2021b), visual participatory approaches can also help depict participants’ personal information infrastructures in everyday life interaction in physical and digital settings. The studies conducted for this article were inspired by such participatory approaches: despite the deviation in participants and research designs from those approaches, these studies shared the general aim of identifying information behavior patterns and engaging participants.

LESSONS LEARNED
The presented case studies implemented visual elements to engage vulnerable participants and sensitively address health-related topics, fostering an environment that encourages open sharing and recall of health information behaviors. The lessons learned involve various aspects focused on the conducted case studies. Generally speaking, one drawback of the participatory approaches within the two presented case studies is that they did not fully meet the criteria for participatory research designs. A truly participatory study would involve broader involvement of participants in various research aspects, ranging from the study's conception to its implementation and analysis. To enhance participation in the case studies presented, the following adjustments could be made, which would also benefit future study designs: Participants should be asked (e.g., through an anonymous survey) about their experience with the visual participatory approach after the interview. For example, it would be worth discussing whether the last task (Figure 5) could be modified to avoid potential perception as a knowledge test. The results of the presented case studies have not yet been applied to solutions that directly benefit the participants. However, it can be seen as a benefit of the first study that participants made use of the Miro boards after the interview, either to discuss content with their psychotherapists or for personal use. All in all, sustaining conversations beyond the scope of traditional face-to-face interviews benefited the depth of the conversation and contributed to gathering rich data. Nevertheless, there is still work to be done to establish researcher-participant relationships that allow for an even more trust-based interaction and also consider the research interests of the participants.

CONCLUSION
The purpose of this article was to provide theoretical outline and practical insights into participatory approaches within health information behavior studies to contribute to a methodological discussion. The descriptive analysis of two health information behavior studies found great potential in implementing visual interactive elements to engage vulnerable participants and sensitively address health-related topics, fostering an environment that encourages open sharing and recall of health information behaviors. The methodological considerations presented were found to be effective for exploring (health) information interactions in an ethically sensitive way, ultimately seeking to involve participants in a more inclusive manner. The approach aimed to actively engage participants within the interview setting through creative and visual elaboration and representation of health information interactions using the virtual whiteboard Miro. Interactive elements embedded in the interview helped to encourage participants to vocalize their thoughts while assessing visual materials. This procedure proved beneficial in making cognitive processes more explicit. In conclusion, using visual materials during the face-to-face interviews facilitated the communication about sensitive health content and supported to capture key statements in situ, promoting the externalization of tacit knowledge during the interviews and lead to gathering rich data. In future work, the analysis of the visual artifacts in conjunction with the interview material, will provide even greater insight into the potential of the method. In addition, the in-depth analysis of the data collected during both studies will be used to further improve the method.

ACKNOWLEDGMENTS
I thank Paulina Bressel and Prof. Elke Greifeneder for together conducting study II, as part of the research project ‘Understanding Disinformation Behavior’ (DESIVE²), funded by the Federal Ministry of Education and Research (BMBF) in Germany (funding code: 16KIS1529). Study I is part of the research project ‘Digital Inclusion in the Context of Social Anxiety Disorder’ (DISA), also funded by the BMBF in Germany (funding code: 13FH536SX7).

Mixed Methods Framework for Understanding Visual Frames in Social Movements

Dozal, Laura W.  
University of Arizona, USA | lwerthmann@arizona.edu

ABSTRACT
Attempting to understand visual frame perspectives in social movement posts online is important to develop an account of how social movements communicate and for what purpose. This paper builds a Mixed-Methods Matrix framework that combines computational applications with visual methodologies to discover frames of meaning making in a large image collection. Frame analysis and Critical Visual Methodology are reviewed and used in the framework to work in tandem with quantitative research methods. The quantitative methods consist of network analysis applications and network structure analysis. Visual sentiment analysis is explored using methods of computer vision. The methods framework is presented in the form of a matrix that enables researchers to identify applications for looking at social movements online through theoretical and computational approaches. The broader implication for the framework is to help researchers understand how online image collections can show meaning through perspective.

Social Movements, Mixed-Methods, Visual Interpretation, Network Analysis, Computer Vision

INTRODUCTION
The Project is a literature review that builds a framework for applying mixed methods for understanding visual frames. The main idea of this review is to select various methods that can extract specific elements of information from images that pertain to social movements. These elements facilitate frames of perception that can create different meanings based on a particular visual interpretation. Frames of perception help create meaning out of particular social experiences that might call for subjective interpretation (Gaffman, 1972). For example, an experience such as a protest can be interpreted through various frames including support of or opposition to an ideology of a social movement; a public policy issue; or a violent action. Although framing has been discussed and described across various disciplines, Mary Bock (2020) describes framing as “a metaphor for contextualisation”. Frames have also been described as a central idea or narrative that can provide meaning to particular events (Gamson, Modigliani 1987, as cited in Rodriguez, Dimitrova, 2016); and can provide context and organization for messages that affect understanding (Rodriguez, Dimitrova, 2016). For the purposes of this review, visual frames can be defined as devices of an image that convey meaning through aspects of association, composition, and social technical elements. Their associational qualities are based on reference and metaphor (Bock, 2020), compositional properties can be indexed or differentiated by other images (Rodriguez, Dimitrova, 2016), and social and technological contexts can aid in explicit understandings of reality.

Forms of visual interpretation used in this review come from Gilian Rose’s (2016) model that reviews methods of visual analysis which include the site of production, the image itself, circulation, and audiencing (Figure 1). Production as a form of visual interpretation contributes to the effects of visual frames based on the technologies used to make that image, the access to those technologies, and the affordances provided by technologies (Rose, 2016). The perception of an image based on its production value can be essential to how a frame is understood, for example the camera used in the 1920s had different technological affordances than a camera in the 1950s, and a camera now. These cameras implement a particular perception of the composition of an image, a record of that point in time, or a falsification of reality (Doisneau, 1991, as cited in Rose, 2016). The Image Itself as a form of visual interpretation can be considered a commodity based on its objective and emotional qualities (Rose, 2016). These qualities can be intentionally or unintentionally perceived through the space and structure of visual effects found in the image (Rose, 2016). Circulation as a form of visual interpretation represents the movement between the production site of an image as well as the site of audiencing (Rose, 2016). Both places can be different in time and environment, but the features of movement between these sites is determined by an image’s circulation (Rose, 2016). For example, the provenance (record of ownership of an art piece) can help curators infer aspects about the circulation of a visual art piece, or the algorithm on a specific social media platform can help shape how an image, for example of daily life or a protest event, is shared. In this review circulation is understood as the technological and social modalities of movement between the image’s production and its audiences. Audiencing of an image is where an interested viewer understands the meaning of an image and accepts or rejects them based on the circumstances of the viewing (Fiske, 1994, as cited in Rose, 2016). The types of technological displays, identifiable elements of an image, and social identities of a viewer have the ability to elicit a particular audience perception (Rose, 2016). For purposes of this research, access to an image, its composition, and social contexts in which it is viewed are all aspects of how a viewer perceives an image and creates an audience.

86th Annual Meeting of the Association for Information Science & Technology | Oct. 27 – 31, 2023 | London, United Kingdom. Author(s) retain copyright, but ASIS&T receives an exclusive publication license.
The interdisciplinary approach to understanding visual frames of social movement images through computational methods has the potential to communicate information on the actions, messages, and causes surrounding a movement by understanding how images are circulated throughout online networks. Although visual framing has been researched across multiple disciplines (Bock, 2020), and frame theory is widely used to review meaning and intentions by social movement researchers, visual frames of social movement are still an under-researched topic, particularly for online images. As online images continue to grow in volume with a velocity that is always growing, and a variety that comes from various authors, they contribute to the big data phenomenon that brings new computational methods of analysis to established theoretical concepts (Gandomi, Haider, 2015). Visual frames have been identified as challenging and have been implemented by various methods that lack methodological basis (Rodriguez, 2020). This research intends to observe some of these methods and identify newer approaches that relate to an interdisciplinary approach of social movement research and data science for identifying visual frames in images online.

**VISUAL FRAMING AND SOCIAL MOVEMENTS: THEORY OVERVIEW**

**Social Movement Frames**

Frames help people make meaning from a situation by helping them organize an experience and perceive aspects of the information (Buechler, 2016). Visual frames can be defined as devices of an image that convey meaning through aspects of association, composition, and socio-technical elements. The influence of visual representations from social movements online has been paramount in spreading awareness for different causes (Meikle, 2015, Michaelson, 2015), but what is their influence towards building a community? As images, videos, and memes about a social cause have become more common for circulating information, these newer types of engagement are understood as activity within the social movement (Earl 2003, Turner, 2013). Roberta Garner (1997) defines social communication campaigns, petitions, and the like (Earl, 2011). As an approach to understand social movement actions and participation, framing is a useful way to appeal to a specific audience and consider existing grievances and cultural issues. In an attempt to explain social experiences, Goffman (1972) strengthened the concept of framing by describing frames as using subjective views to understand specific “slices” of an empirical world (Davis, 1975). Framing was introduced to the field of social movement research as a social constructivist approach for meaning making and meaning interpretation. In social movements, framing puts forward cultural components that review the
social construction of meaning by paying attention to grievances, motivation, recruitment, and identity in the context of collective action (Buechler, 2016). Social movement framing helps to conceptualize the work of mobilizing grievances and relies on an interpretive process that pulls from current events and culture.

Framing research developments include qualitative and quantitative methods for researching recruitment and participation, framing disputes, discursive fields, and communication efforts. With regards to using frames in social movement recruitment and participation processes, David Snow, et al 1980, apply a systematic review to three sets of data collected from previous case studies, recruitment documentation, and questionnaires to better understand process details, as opposed to the previously analyzed psychological and motivational levels of analysis. The data come from various types of movement organization structures, and the findings show that recruitment efforts are based around structural proximity, availability, and affective interaction (Snow, 1980). Community outreach structure was also found to be an important factor for recruitment strategies and growth. Further research would do well by applying this systematic approach at scale, and with digital technologies in mind. One example of framing in a digital recruitment process introduces the notion of distributed citizenship, where users define their part of their online identities as citizenship of groups online which assumes a creative political relation within networks to one’s contemporaries, specifically with social media (Meikle, 2016). Examples of early distributed citizenship are interactivities of do-it-yourself (DIY) cultural-political online communities that show a need for a type of “real” digital citizenship. Although this essay provides examples of distributed citizenship, there is no concrete methodology to prove the need or existence of it. Data collection might benefit from digital communication technologies by enabling a wider range of data collection processes to relevant participants in close proximity and those at a distance.

Research on using framing theory for communication efforts considers digital technologies for social movements. Earl et. al. (2016) review literature in political communication and social movement studies and suggest that the two fields be integrated for a better understanding of audience reception and context of social movement messages. Specific topics that would benefit from this collaboration include “information overload, selective attention, perceptions of bias, and the possibilities that entertainment-related communications open up, among others” (Earl, et. al 2016). This study helped show different aspects of messaging in social movements, specifically in recruiting for protest participation, but only goes in-depth on the medium of the message i.e. digital vs face to face, instead of the content.

Visual representation of social movements online provides information on the actions, messages and causes supporting the movement, with an intention of raising awareness and building support. In some cases, challenging an oppressor or state is part of the message (Earl, 2011). An online visual representation of a social movement is ephemeral and contingent on performance and actions, similar to descriptions of street art (Irvine, 2012). Online images can record actions and traces of the movement’s message, which have persuasive and recognizable elements of collective action that can be reflective of visual frames. This review of social movement image analysis understands that types of connections within the group can help to identify visual frames in social movement images online. Visual frames in social movements have been a foundational methodology in the field of research that implements notions of meaning making and goal setting for movements and their members. Framing as devices to convey meaning through elements of association, composition, and social and technical components, can create outlets for different methods of visual interpretation.

Social movement framing can be conceived in digital technologies by understanding the content used. The literature on communication and recruitment efforts discusses the affordances of digital technologies (Gregory, 2018), text data including documents and online communications (Bail, 2012; Earl, 2014), and models that can be applied to understand the frames being reviewed (Freelon, 2018; Tufekci, 2014, 2017). Specifically, if we review how images and video content are implemented in collective action of social movements, and include aspects of discourse and composition, there is potential to identify elements of frames being used. These frames can be understood as forms of visual representation of a social movement’s meaning construction and goal alignment, they can also review framing efforts at a more granular level.

**Visual Interpretation Modalities**
Rose’s four sites of visual interpretation modalities are used in this research as a framework for using frames to interpret images that portray actions, events, and messaging from social movements online.

- **Production** as a form of visual interpretation contributes to the effects of visual frames based on the technologies used to make that image, the access to those technologies, and the affordances provided by technologies (Rose, 2016).
- **Circulation** as a form of visual interpretation is understood as the technological and social modalities of movement between the image’s production and its audiences. Both places can be different in time and
environment, but the features of movement between these sites is determined by an image’s circulation (Rose, 2016).

- The Image Itself as a form of visual interpretation can be considered a commodity based on its objective and emotional qualities (Rose, 2016). These qualities can be intentionally or unintentionally perceived through the space and structure of visual effects found in the image (Rose, 2016).
- Audiencing of an image is when an interested viewer understands the meaning of an image and accepts or rejects them based on the circumstances of the viewing (Fiske, 1994, as cited in Rose, 2016). The types of technological displays, identifiable elements of an image, and social identities of a viewer have the ability to elicit a particular audience perception (Rose, 2016).

Visual Interpretation Approaches

Visual representation of online social movements can be understood through concepts of visual culture, visibility, and notions of ephemerality used to represent social practices and locate deviations from the quotidian. According to Margaret Dikovitskaya (2021) visual culture is “a research area and a curricular initiative that regards the visual image as the focal point in the processes through which meaning is made in a cultural context”. By specifically focusing on visual discourse in framing research, Rodriguez and Dimitrova (2016) identify levels of visual framing from different types of media content and its audience’s perception through a literature review. Their literature review focuses on the gaps in identifying frames in news discourse, and how the visual aspect of frames is more powerful than text because of a “lack of cognitive load” (Rodriguez, Dimitrova, 2016). They research how visual frames have been used in the past and how they can be analyzed in the future by developing a model of systematic frames including denotative, stylistic-semiotic, connotative, and ideological representations (Rodriguez, Dimitrova, 2016). The amount of information provided by a visual in one instance is colossal, especially with concrete framing elements. Although less thinking is needed to understand a visual with intentional messaging, if concrete references towards visual interpretation are lacking it can be harmful to the process of making meaning through visual interpretations. The authors touch on this subject and describe it as having specific referential implications for intentional messaging by specific parties (Rodriguez, Dimitrova, 2016). Mary Bock (2020) goes deeper into concrete theoretical applications of visual framing by proposing a model that uses specialized visual approaches opposed to language approaches. Block’s analysis applies a literature review that covers 165 articles, conference papers, dissertations, books etc to understand the creators of a visual frame, the material practices behind framing, and how the image works as a form of ideology (Block, 2020). Essentially, Block’s model covers production as a site of meaning making and falls short of including aspects of circulation and audiencing. Other research on visual frames spans across the four sites of meaning making by analyzing various types of framing approaches. Framing applications cover a wide range of topics that affect specific types of visual analysis, specifically pertaining to issues pushed by social movements. These applications can be viewed through aspects of the four visual interpretation modalities as sites of meaning making.

NETWORK ANALYSIS AND GROUP STRUCTURE: THEORY OVERVIEW

With regards to the visual interpretation model, identifying patterns of ties and group structure of images connected through online social movement actions can be paramount in finding visual frames regarding circulation and production. Circulation can influence group structure as movement of an image throughout a group has the potential to be part of a significant social, cultural, and political process (Rose, 2016). While using circulation to analyze patterns of ties, identifying the strength of nodes and their relationships to other nodes can be helpful in finding information circulation hubs that enable a larger or smaller spread of visual frames (Goldenberg, Han, Lehmann, Hong, 2009, Granovetter, 1973). The affordances and infrastructure of the social media platform enable specific forms of production practices that evoke various digital implications of re-sharing. These infrastructures for image production practices are helpful to identify common patterns of ties and structure within groups. For example, liking and resharing features are part of the algorithmic rules that can guide group formation and node relationships.

Group Formation

A group in a network is identified by the presence of ties within a network, both direct and indirect, as well as identifying full connections between individuals within a group, and complete isolation across groups (Hoffman, 2021). A group can be as small as two nodes with one connection, or as large as a million nodes with millions of connections, and at the most basic level, every node is reachable through a path by every other node (Hoffman, 2021). Mario Diani (2003) introduces the idea of a social movement being a specific type of social network based on specific types of relations formed within and between movements which can range from coalitions, solidarity campaigns, political organizations, and even countermovement (Diani, 2003). This idea is expressed through implementation of group identification, structure, and formation within social movement networks. Backstrom et al. (2006) attempt to understand the structural features and formation of groups within online communities, and how these groups change over time. Although the study was done before the heightened interaction of social media affordances, the study looks at links between users and finds that particular individuals and structural connections.
enable growth of an online community (Backstrom, 2006). This article is important for implementing a methodology that measures movement of a group within a network and for understanding how that movement is aligned with changes in the overall network structure (Backstrom, 2006).

Group formation and structure can infer potential sites of production and how access to social media platforms and the affordances provided by them can give insight on how information is spread based on how nodes might have more or less power over network connections. As a method for group formation and identifying group structure, stochastic blockmodels can be used in the Mixed-Methods Matrix framework. Stochastic Blockmodels can be applied to analyze the community structure of networks, which in turn can enable underlying implication of the overall social structure (Brieger, 2004; Cole, 2019). In this case, instead of finding nodes who share the same set of ties, stochastic blockmodels find nodes that share similar positions within their groups (Hoffman, 2021).

**Diffusion Practices**

One of the more influential theories of diffusion practices is the diffusion of innovation, or ideas and how they are adopted by specific individuals and communities. The concept is best explained by understanding that there are levels to how an idea might spread from early adopters, a majority and laggards (Rogers, 2013). Communities can be connected from a hierarchical mode, “top-down”, or proximal mode, where nodes connect to others that are spatially or culturally relevant, and maintain similar sharing behavior (Soul, 2004). Nodes can be connected using direct or indirect ties. Direct and indirect ties are important in exploring particular outcomes of information diffusion, for example, direct ties can facilitate ideological frames and protest tactics to be shared between different social movement communities while indirect ties are important to help spread a cultural understanding of values and ideas between similar nodes that might not have direct contact (Soul, 2004). These concepts can be applied to help understand how visual frames are spread throughout social movement networks.

An attempt to identify the position of a node and its structure in a network can be explored through positionality which is the analysis that looks at similar patterns of relations to see nodes that might occupy similar positions and perform similar functions in the network (Hoffman, 2021). This positional analysis is helpful for identifying nodes with the potential to circulate information to a larger or smaller network. Such nodes, or even subgroups of nodes, are called hubs and rest on their central positioning and acquaintance connections (weak ties) to spread information in an efficient and effective manner (Granovetter, 1973; Onnela et al., 2007; Wasserman, Faust, 1994).

**Deep learning overview**

Particular qualities of an image, both physically and symbolically, have the ability to shape meaning. One way to understand the components of an image is to look more closely at its compositionality and understand the semiological effects it might have on building visual frames. Deep learning, or neural networks can do this for a large image dataset. Deep learning tasks mainly consist of algorithmic methods for mapping an input vector to an output vector using layers of mathematical transformation that help process parameters and apply weights to the data (Goodfellow et al, 2016).

One of the more common deep learning applications for image methods is the Convolutional Neural Network (CNN or ConvNet) algorithm. A CNN processes input data with grid-like topology including images that have a 2-D grid of pixels (Goodfellow et al, 2016). The model then discretizes the data at regular intervals to assign learnable weights as importance to differentiable aspects of the image (Goodfellow et al, 2016, Saha, 2018). These weights help differentiate parts of the image and with enough training the process can learn specific filter types for classification. These filters represent features that can be adapted through training, effectively learning a set of features appropriate for the task, in our case, a set of features that represent the image. Essentially, the CNN model learns a collection of filters, each of which adjust its weights to highlight local relationships that can occur anywhere in the image. The collection of these filters are combined with a nonlinear function where many layers of the filters can be composed (Morrison, 2021). The CNN model is most used throughout the following research review and is applied in combination with other types of classification and feature extraction and word embedding models. These models are then put through a classification model, most of the articles in this review use a support vector machine (SVM) as a sentiment classification model (Kumar et al, 2020; Kumar, Jena, 2021; Oritis et al, 2021; Sajjad, Muhammad, et al, 2018). A support vector machine learns to assign labels to data based on what it learned in the training set (Nobel, 2016). As more labels are applied, the model learns how to tag the data and applied classification tags with more confidence (Gandhi, 2018).
Visual Sentiment Analysis
Sentiment analysis can be used to computationally categorize messages and attitudes based on the text. It is supposed to decide the sentiment of a text scored on a positive or negative effect based on a chosen sentiment corpus used in a model. Emotions and affect can be represented by signs and qualities of an image (Rose, 2016). For the purposes of this paper, the multimodality of the image as well as any textual elements attached to it can both be used for sentiment applications.

VISUAL INTERPRETATION MATRIX FRAMEWORK
The application of the combined methods for visual interpretation can identify the influence visual frames might have on a group based on the affordances of visual creation provided by a platform, as well as access to that platform. It also can aid in identifying types of frames that frequently circulate specific network structures. A review of methods incorporating the image itself and audiencing as forms of meaning making can aid in the compositional aspect of an image and how it can be perceived. The combination of methods is implemented into the visual interpretation matrix (Figure 3) which shows the computational applications that coincide with the sites of visual interpretation modalities. Each cell holds the application that describes the method which enables meaning making. The site of production can be a host for initial group formation while using stochastic blockmodels. The site of circulation can be interpreted through diffusion practices consisting of Exponential Random Graph Models (ERGM) and positional analysis. A suggested application to review the image itself is through image analysis with computer vision, more specifically using neural networks. The site of the audience can be reviewed through both diffusion practices of community structure network analysis and natural language processing methods in sentiment analysis.

Information Diffusion and Group Formation
Network and frame analyses are included in the core concepts of social movement research, but to date, few studies combine the two. The collaboration of both network analysis and visual framing can help to understand aspects of group formation tendencies based on the visual content being circulated online.

Visual frames at the sites of circulation and production can be looked at through the lens of diffusion practices and group formation. Diffusion practices deal with how information spreads throughout communities and have been theorized based on how types of information spread, for example innovations (Rogers, 2003). Group formation looks at processes of how communities come together to develop over time (Backstrom et al, 2006); this concept can be applied to online and offline communities. These concepts are used in network analysis methods and can be applied to online and offline content. Network analysis focuses on the patterns of ties between nodes or individuals (Hoffman, 2021), and is useful to understand social movement communities. Network analysis for social movements can also help understand patterns of visual framing within the content being shared in and across communities.
These patterns can be viewed in the context of qualitative and quantitative applications of diffusion practices and group formation.

**Figure 3: Proposed Mixed-Methods Matrix**

**Connecting Sites of Production to Group Formation**
Understanding the intricacies of structure and group formation can be key to identifying the particularities of groups within a network and might help the spread of information and framing effects for meaning making. By using group formation methods to explore the site of production, many researchers have attempted to combine stochastic blockmodels with other models to understand various positionalities and relational structure for different types of data. These approaches have been reviewed as extensions to community structure estimation methods (Nicola et al, 2021). For example, Cole and Williamson (2019) used count-based topic modeling and the stochastic blockmodel to understand relations within and across latent communities by reviewing the information being sent between nodes and groups. Another approach has been to review how stochastic blockmodels work with extensions of graph clustering. A literature review and comparison of types of graphs, clustering, and inference approaches, as well as number of group applications is investigated in a systematic and cross-sectional way, finds that the Stochastic blockmodel incorporating a Markov Chain Monte Carlo with a hierarchical structure showed positive developments for applications on graphs (Lee, Wilkinson, 2019). Markov Chain Monte Carlo applications are used to understand the probability distribution of a population by sampling from the distribution (Geyer, 1992), in this case the nodes were connected in a hierarchical structure instead of by proximity connections.

**Connecting Site of Circulation to Diffusion Practices**
Understanding the intricacies of structure and group formation can be key to identifying the particularities of groups within a network and might help the spread of information and framing effects for meaning making. Using methods of positionality in a network as diffusion models can enhance visual modalities of circulation. To review the information being spread within groups across networks, Yongjun Shin (2020) looks at how tripartite semantic networks can be used to understand message frames. A tripartite network reviews how three different types of groups can be connected by levels or proximity (Farraro, Doreian, 1984). By looking at differences in message framing over time, Shin (2020) applied the tripartite semantic network analysis to show small and significant differences in framing mechanisms based on network structure. Although the article does not focus specifically on visual frames, the implication of a tripartite analysis on understanding group formation and structure is an important addition to understanding circulation frames of images in a network.

Exponential Random Graph Models (ERGM) can be considered to identify diffusion practices of information throughout a network because they can control for many factors, not just node attributes. ERGMs use the observed network as a sample network to be seen as one instantiation of a set of possible networks with similar features as (weighted) parameters, including direct and indirect ties and node attributes, and maximizes the probability of the
observed network over other (usually thousands) similar generated networks (Cranmer et al., 2017; Hoffman, 2021; Luke, 2015). ERGM models can also be used to understand social roles within groups and how they facilitate information by focusing on the more prominent nodes specifically with ego-ERGM which helps model potentially latent dynamics of distinct roles and can help predict if an organization in question takes on a particular leadership role (Box-Steffensmeier et al., 2018). Extensions to ERMGs have recently been introduced to understand multiple relationships and interaction within groups, specifically groups with more than one type of relation or interaction, also understood as multilayer networks (Krivitsky et al., 2020). Group formation and group structure can infer potential sites of circulation and how access to social media platforms and the affordances provided by them can give insight on how information is spread based on how nodes might have more or less power over network connections.

**Computational Applications for Sites of Audiencing and the Image**

Visual frames for social movements online are derived not only from components of the image, but also how the viewer understands the meaning of an image. Compositional and social modalities derived from particular qualities of an image, aid in understanding the meaning making process through the image itself. Visual frames can add attention through audiencing in the form of convergence, where a paradigm shift is reflected through changes from medium specific content to content that can be consumed across multiple forms of digital tools (Jenkins, 2008, as cited in Rose, 2016). For example, heatmaps of the spread of Covid-19 have converged as a form of understanding levels of infection and have been seen not only on various social media platforms, but also in newsrooms, research outlets, and websites (Pan et al., 2020). The heatmaps were a result of consistent use by the audience and reflected how the data analysis application of visual cues enable a clearer understanding for the general public.

Network and frame analyses are included in the core concepts of social movement research, but to date, few studies combine the two. The collaboration of both network analysis and visual framing can help to understand aspects of group formation tendencies based on the visual content being circulated online. The application of the combined methods for visual interpretation can identify the influence visual frames might have on a group based on the affordances of visual creation provided by a platform, as well as access to that platform. It also can aid in identifying particular types of frames that frequently circulate specific network structures. A review of applications incorporating the image itself and audiencing as forms of meaning making can aid in the compositional aspect of an image and how it can be perceived. These methods can be understood through sentiment analysis and Deep Learning approaches.

**Connecting Sites of Audiencing and the Image to Deep Learning**

To supplement textual sentiment analysis of protests, a visual CNN model that recognizes protesters’ activity and attributes to estimate levels of perceived violence is implemented on data collected from online images of protests (Won, Joo, Steinert-Threlkeld, 2017). The research results in high accuracy measures of sentiment review as well as a protest image dataset of geotagged tweets to analyze visual attributes and sentiments (Won, Joo, Steinert-Threlkeld, 2017). Although the visual analysis captures general depictions of image characteristics to understand the overall sentiment of protests events, implications of privacy issues might arise, especially because of the geotagged data. Conversely, understanding the level of perceived violence at events of collective action has the potential to support the group and their outer networks in understanding the levels of danger in an event.

Deep learning methods have also been used in attempts to recognize collective action, disaster images, and other topics in the social sciences. Disaster images have a huge circulation on social media during and after the time of the event. The diversity of images that cover the disasters is helpful to build a benchmark corpus of categorical images for a deep visual sentiment analyzer (Zohaib Hassan et al., 2020). Other research reviews visual content for political science through automated methods of analysis, computer vision and deep learning, can contribute to new research questions and methodology to the field of political science (Joo, Steinert-Threlkeld, 2018). These advancements are helpful in applications of social movement analysis, as the field is connected to research in political science (Earl, 2000), and might have the potential to support visual frame analysis in the future.

**MIXED-METHODS MATRIX USE: INTERDISCIPLINARY IMPLICATIONS**

These applications are suggestions and examples for how to use the Mixed-Methods Matrix, which can be used in whatever creative manner a researcher deems appropriate. The Mixed-Methods Matrix attempts to provide successful mixed method applications for identifying visual frames, first for social movement images, and for other domain specific image datasets. Implementing mixed methods through visual interpretation approaches to find visual frames of social movement images can enable information extraction, classification, and interpretation through quantitative analysis. It can also provide a theoretical framework of perception as meaning making through visual frames. The Mixed-Methods Matrix contributes to the creation of a methods framework to better understand the implications of computational approaches in visual theory. Theorizing the application of these approaches can
inform actual experimentation on large amounts of data to see if outcomes exhibit a visual frame based on the visual interpretation methods.

Attempting to understand visual frames in social movement posts is necessary to develop a model of how social movements communicate online and for what purposes. Tools like the Mixed-Methods Matrix can be used to identify types of information spread online. Plenty of research has been done on digital technologies in social movements (Earl, Kimport, 2011; Tufecki, 2014) and how movements deal with problems that are seemingly similar to historical obstacles in the past (Earl, 2014); but communication, recruitment, and campaign processes online has implemented new approaches to collective action on and offline. As more of our lives move to online communication and we become more adapt to large amounts of data, the ability to understand how to become part of a movement, stop a violent event, or spread awareness is pertinent, especially when false information is now a normal part of online communication (Zanettou et al, 2017). Applying an extra filter of framing to how we perceive the meaning of messages can enable a viewer with added information on how to interpret an image online.

CONCLUSION
Visual frames in social movements have been a foundational methodology in the field. Framing can be used in various ways to reinforce established research methods including visual analysis through network analysis and deep learning. To understand frames of visual analysis, four modalities for interpreting visual materials are applied as a framework to understand how computational application might work to identify visual frames. The four sites include production, the image itself, the site of circulation, and sites seen by audiences (Rose, 2016). The applications of visual analysis are applied to social network methods including Exponential Random Graph Models, or ERGM to observe a network as a sample over a set of simulated possible networks to understand the structure of a network that enables information diffusion. Where stochastic blockmodels can be applied to analyze group formation to understand social structure. The review of these analyses is intended to understand how images connect to each other based on the content, viewers, and creators. Deep learning analysis methods consist of visual sentiment analysis using feature extraction and word embeddings using semiotics elements based in signs.

Future research on the ethical implications of using visual methods in collective action or social movement research is necessary for protecting the privacy and safety of social movement members. Especially since visual and location information is vital to the ethical implications of collective action events that might become dangerous. Also, future considerations of online censorship regarding visual content analysis is important for understanding how frames are built around specific types of compositionality. The methods and computational applications here do not cover aspects of the ethics of visual content, but the topic is appropriate for those attempting to replicate the Mixed-Methods Matrix.

ABSTRACT
This study evaluates the effectiveness of various readability measures when assessing the difficulty of film materials for English Language Learners (ELLs). Library materials catering to ELLs are frequently limited to formal instruction texts and fiction materials. This study explores the feasibility of less laborious, computational text assessment methods to better understand library holdings from the perspective of ELL appropriateness. The investigation applies traditional formulaic readability measures and modern cohesion methods to film subtitle data. While text difficulty assessment with readability measures has been widely studied, there is a need to investigate which measures are most suitable for film application. In addition to evaluating existing readability measures, a more robust composite score is also presented, combining aspects of traditional readability formulas and modern cohesion methods. The experiments were conducted on real-world datasets and tested on film data marked for difficulty by ELLs.

KEYWORDS
readability, language learning, film difficulty, recommendation

INTRODUCTION
Over the past decade, there is growing desire for libraries that serve the increasingly diverse population of English Language Learners (ELL) within their respective communities (Foster, 2018). Public library environments are safe havens for users of different ELL backgrounds. Recent migrants benefit from these institutions as being a place to gain English instruction and support resource acquisition (Wexelbaum, 2016). However, the COVID-19 pandemic has highlighted a greater need for digital services and support beyond in-person interactions. The limitations on in-person communication can elicit an additional challenge for library professionals and users alike when providing material guidance, such as readers’ advisory (Lockley et al., 2021).

Existing methods of recommending resources for English Language Learners (ELLs) generally consist of either pre-compiled lists that assign difficulty by professional judgment (Moorhouse, 2020; Vardell et al., 2006) or materials that are specifically produced for ELLs that use levelling criteria to indicate difficulty and planned progression (Chou, 2022; Vuzo, 2023). These methods have been widely used in the field and have been shown to be effective in providing appropriate resources for ELLs; although it is essential to note that they should be used in conjunction with other strategies and considerations to ensure that ELLs have access to the most appropriate resources. Despite this, it is also important to acknowledge that these methods have limitations.

While current methods for constructing content recommendations for ELLs are valuable, they are hindered by quantity and medium: which means these materials only represent a fraction of a library’s holdings and are also confined to text materials. Further, they are restricted to specific written text registers such as narrative texts like novels or expository texts like formal instruction; this offers limited flexibility in choice on the user’s end. This begs the question of how the full extent of a library’s collection can be better utilized through the lens of ELL appropriateness. By doing so, libraries can bridge the gap between generalized recommendations to more audience-specific and personalized advisory lists.

One approach to expand content recommendations for ELLs in libraries is to implement readability measures that assess the complexity of other English-language texts. Readability, while not universally embraced as a phenomenon, is the perception of ease when reading a text by an individual (DuBay, 2004). There are numerous methods of assessing readability, but they can generally be thought of in two ways. First, traditional readability formulas such as Flesch Reading Ease (R. Flesch, 1948) and the Flesch-Kincaid formula (Kincaid et al., 1975), operate under the surface level features like word, sentence, and syllable counts. Second, modern cohesion methods like the Coh-Metrix L2 Readability Index (RDL2) (McNamara et al., 2014) that go a step beyond traditional formulas and are trained on deeper natural language processing (NLP) features.

Readability measures are sometimes used to match users to text materials. For example, the Flesch Reading Ease (R. Flesch, 1948) was designed to assist in matching users with schoolbooks, whereas the Linsear Write Formula (O’Hayre, 1966) was suggested to aid in the assessment of government technical manuals. Although these formulas were developed for written text, there has been evidence dating back near to the inception of popular formulas like...
the Flesch Reading Ease, denoting how these formulas might be even more suitable for spoken media over the written medium (R. F. Flesch, 1951). The use of readability measures as an assessment for films specifically for ELLs is sparse. New research into the area of matching low-literacy users with films based on caption data has demonstrated promising results (Pantula & Kuppusamy, 2020).

A recurring concern in research on the use of films as an ELL resource has been on identifying relevant resource selections that are both correctly paired with ELL comprehension level and engaging (King, 2002; Tuncay, 2014). Readability measures can facilitate matching users with resources that align with their proficiency while preserving their ability to choose content from a breadth of topics and genres. Beyond the content that readability measures can assess, other factors relating to listening comprehension can be acknowledged and assessed when evaluating films for ELLs. These factors expressed by Gilakjani and Sabouri (2016) primarily relate to listening comprehension and include features associated with the length and speed of speech production in addition to the accent or dialect expressed in the film.

There is potential to improve information access and aid resource acquisition for ELLs by enriching the metadata of existing library collections. Readability measures can facilitate the assessment of a film’s perceived difficulty, and this information can be incorporated into existing library metadata records.

An advantage of applying existing readability formulas and measures to film for ELLs is that these methods are computationally tractable and, compared to expert-recommended materials, they allow for broader coverage at much lower cost. However, the tradeoff is that assessment variables are largely limited to surface-level features that may not provide a thorough enough examination of the material. To understand the value of different existing measures for film, we investigate and compare a series of different measures.

Beyond readability and text cohesion measures, other film-specific information can further enhance the assessment of text difficulty in films. For example, Pantula and Kuppusamy (2020) found that incorporating a temporal dimension, specifically through the use of an Average Time per Frame (ATPF) variable, effectively assesses difficulty through subtitle data. In this study, we incorporate the average number of words per second derived from the film’s associated .SRT text file to account for a temporal dimension.

This study investigates the effectiveness of traditional readability formulas and modern measures in assessing the difficulty level of film materials for English Language Learners. Specifically, the research questions for this study are as follows:

**RQ1:** How do different readability formulas correlate when applied to film text, and how do these correlations relate to film's critical ratings and genres?

**RQ2:** Can readability measures and associated features, such as sentence length, word frequency, and vocabulary difficulty (among others), be used for tagging film appropriateness for ELLs?

While the readability formulas and cohesion measures have been studied with respect to text, it is valuable in the context of libraries to understand how these calculations relate to text derived from film. By investigating relationships between formulas and subtitles, we can better understand which specific variables appear to be influential factors for target ELL audiences.

**RELATED WORK**

**Readability Measures for ELLs**

Readability formulas were implemented as a mechanism to help assess the difficulty of textual materials and assist practitioners in appropriate selections that correspond with a learner’s comprehension level. Research in the areas of appropriate material pairing (Peregoy & Boyle, 2016; Qodir et al., 2016; Wu, 2014) have indicated the importance of connecting learners with balanced resources that promote progress for language development without being overly challenging. This difficulty can result in discouraged student participation or failing to not actively engage participants.

Readability measures, such as traditional formulas, possess limitations and are often met with criticism surrounding their validity. These issues predominately relate to the confines of the surface level features being calculated (Klare, 1976). The consensus from advocates of these formulas is expressed in their ease of implementation and interpretation: meaning they can be generated with relative ease, and they provide a score that can be easily understood by a user. However, they are limited in scope with regards to deeper factors associated with ELLs, those being features of context or text cohesion (Zamanian & Heydari, 2012).

Progressive research into readability measures designed for ELLs has been demonstrated with the advent of more sophisticated tools harnessing NLP techniques to investigate deeper features of associated text difficulty for ELLs.
Recent studies comparing traditional formulas with modern methods have indicated that measures like the RDL2 are more accurate predictors of perceived text difficulty for ELLs (Crossley et al., 2011; Nahatame, 2021).

**Film as a Resource for ELLs**

Film as a linguistic pedagogical resource resonates with the notions of the cognitive theory of multimedia learning (CTML) (Mayer, 2014), dual-coding theory (DCT) (Paivio, 1971), and bilingual dual-coding theory (Paivio & Desrochers, 1980). Multimedia-based approaches to learning for ELLs utilize various cognitive stimulation forms which work together to render more effective learning retention. The effectiveness of this strategy has been demonstrated to have a positive effect, particularly with listening comprehension in ELLs, as the associated visuals of actor portrayals and circumstantial cues of a film “can provide context and non-linguistic input to activate topon-down processing” (Vandergrift, 2007, p. 200).

Beyond gaining exposure to phonological components of language usage, films also provide awareness into language expression that is culturally dependent, a salient example being colloquialisms. Researchers Abolfazli Khonbi & Sadeghi (2017) found film to be the best non-interactive mode of teaching idioms to ELLs with only interactive role-playing demonstrating better results.

An advantage of utilizing film to promote ELL development is that these resources offer a high degree of flexibility for both educators and users in their ability to be manipulated via user controls (i.e., the ability to pause, stop, play, and rewind a film) and their inclusion or exclusion of subtitles and captions. Researchers Albiladi et al. (2018) have suggested that these resources can alleviate specific pressures associated with formal instruction while providing an authentic representation of linguistic expression that promotes cultural awareness which would otherwise be challenging to perceive in traditional educational media, such as in textbooks.

**Using Subtitles and Captions to Assess Difficulty for ELLs**

Traditional readability formulas and modern cohesion methods alike have been devised for the assessment of text mediums such as books, with limited studies into their implementation of video subtitles. Though, research is expanding in this field. Some advancements have been made into models designed for aligning film to low-literacy users based on features of sentence and word ambiguity, indicating a high degree of difficulty prediction accuracy (Pantula & Kuppusamy, 2020). Further, recent developments by Alghamdi et al. (2022) indicate promising results applying NLP regression techniques that utilize acoustic, lexical, and syntactic features. They demonstrate results that outperform the Flesch Reading Ease for the assessment of lecture video subtitles.

Whereas research is limited in using automated techniques to evaluate perceived difficulty of films for ELLs derived from subtitles, the broader scope of applying subtitles for ELL development is well researched often with varying results. Vanderplank’s (2010) review coalesces the notion that subtitles generally are a net positive for ELLs, although considerations may be warranted as to what type of subtitle (i.e., reversed, bimodal, or standard) is most suitable for a particular ELL. In their review of authentic video materials for ELLs, researchers Baicharoen and Boonyaprapak (2018) found subtitles to have a significant impact on ELL listening comprehension, while further acknowledging that flexibility of choice as when to use subtitles should be case dependent based on the objective of the learner or educator.

The most appropriate approach for utilizing captions or subtitles with ELLs is best determined based on the specific needs of the user. Therefore, for the purpose of this exploration, subtitles are solely used as a method for assessing associated difficulty of the language represented within a film. Using readability measures on subtitle data aligned with their respective films offers one method of assessing the difficulty of a particular resource. Though, there are additional elements accompanying films that may be beneficial to ELLs, such as the inclusion of metadata relating to the pacing or rate of dialogue expressed in a film.

**READABILITY MEASURES**

**Traditional Readability Formulas**

The many existing measures and respective variables for determining the difficulty of text can be broadly categorized into two categories: those that assess syntactic complexity and those that assess lexical complexity. Some common variables or features that are often used in the calculation of traditional readability formulas include:

- **Syntactic features**: such as the number of words per sentence or the total number of sentences, which are used to indicate the level of grammatical complexity.

- **Lexical Features**: such as the number of characters per word and the number of syllables, which are used as a substitute measurement for lexical density, or frequency counts of vocabulary associated with 'difficult' words. These measures are used to indicate the level of vocabulary complexity.

For this investigation, seven traditional formulas are selected:
**Flesch Reading Ease (FRE)** – This metric scores the difficulty of a textual material on a scale from 0 (Most difficult) to 100 (least difficult) and is based on the dynamics of the average sentence length and the average number of syllables per word within the text:

\[
206.835 - 1.015 \left( \frac{\text{total words}}{\text{total sentences}} \right) - 84.6 \left( \frac{\text{total syllables}}{\text{total words}} \right)
\]  

(1)

**Flesch-Kincaid Grade Level (FK)** – Based on the same principles as the Flesch Reading Ease score, this metric uses the same variables of words, sentences and syllables. This calculation slightly deviates from the FRE and performs a simple metric relating to an expected U.S. grade level:

\[
0.39 \left( \frac{\text{total words}}{\text{total sentences}} \right) + 11.8 \left( \frac{\text{total syllables}}{\text{total words}} \right) - 15.59
\]  

(2)

**Gunning Fog Scale Level (GF)** – This metric employs the variables of words, sentences, and complex words (those with 3 or more syllables) and is calculated as in equation 3, rendering a hierarchical result where higher values denote more difficult reading materials:

\[
0.4 \left( \frac{\text{total words}}{\text{total sentences}} \right) + 100 \left( \frac{\text{complex words}}{\text{total words}} \right)
\]  

(3)

**SMOG Grade (SMOG)** – This measure only focuses on two variables: the number of polysyllables and the number of sentences. Higher scores indicate a more difficult text:

\[
1.0430 \sqrt{\frac{\text{all polysyllabic words} * \frac{30}{\text{number of sentences}} + 3.1291}{\text{number of sentences}}}
\]  

(4)

**Automated Readability Index (ARI)** – This measure computes the ratio of the characters per word and words to sentences. Higher scores denote more difficult texts.

\[
4.71 \left( \frac{\text{characters}}{\text{words}} \right) + 0.5 \left( \frac{\text{words}}{\text{sentences}} \right) - 21.43
\]  

(5)

**New Dale-Chall Score** – This measure includes the variables of words and sentences, similar to the above formulas. However, it differs by incorporating a list of 3000 familiar words (i.e., understood by 80% of fourth-grade students). Higher scores denote more difficult texts:

\[
0.1579 \left( \frac{\text{difficult words}}{\text{words}} \right) * 100 + 0.0496 \left( \frac{\text{words}}{\text{sentences}} \right)
\]  

(6)

**Linsear Write Formula** – This formula, designed by the U.S. Air Force, was designed to assess the readability of technical manuals. Higher scores denote more difficult texts.

\[
\frac{(\text{easy words}+1) + (\text{hard words}+3)}{\text{number of sentences}}
\]  

(7)

Where easy words are denoted as two syllables or less and hard words are three syllables or more.

**Specific Measures for Assessing Readability for ELLs**

**Complexity Score**

*Common European Framework of Reference (CEFR) (Europarat, 2020)* – This automated formula is based off the CEFR language proficiency standard. These models utilize artificial intelligence to help calculate the perceived difficulty of individual words within a text. The percentage of difficult words are then calculated, and a cumulative score is generated to correspond to an individual’s proficiency level. Difficulty scores correspond with the CEFR framework ranking difficulty from easiest (i.e., A1) levels to most difficult (i.e., C) levels. The complexity score considers the proportion of words as represented in categories ranging from A1-C.

**Coh-Metrix**

*Coh-Metrix L2 Readability (RDL2) score* (McNamara et al., 2014) – The most computationally sophisticated formula included for this list construction, the Coh-Metrix v.3.0 analyzes 10 indices to establish a Coh-Metrix L2 readability score. The variables being calculated are listed as: content word overlap, adjacent sentences, proportional, mean (CRFCWO1); sentence syntax similarity, all combinations, across paragraphs, mean (SYNSTRUT); and CELEX Log minimum frequency for content words, mean (WRDFRQmc).

\[
-45 + (52.230 * \text{CRFCWO1}) + (61.306 * \text{SYNSTRUT}) + (22.205 * \text{WRDFRQmc})
\]  

(8)
An examination of the various traditional readability formulas and methods specific to English Language Learners (ELLs) reveals the relationships between measures, as illustrated in Table 1. It is evident that there is a substantial overlap of shared variables among traditional formulas.

Table 1. Listed readability measures that are tested and their associated variables.

This paper offers an analysis into how readability measures can be adapted to process film materials through existing associated subtitle .SRT data and demonstrate a proposed solution in increasing library holdings for ELLs.

**DATA**

For this analysis a diverse set of films were selected with respect to genre and representative of popular titles that are likely to be in demand by library users and are more likely to exist in a library's collection. To achieve this, subtitles for IMDB's top 250 English films through the year 2016 were processed (Users, n.d.). The subtitle data for the collected 250 films were sourced from OpenSubtitles.org in the .SRT format. Submissions to OpenSubtitles are user-based, and films have numerous associated .SRT files. To ensure the most accurate .SRT file was selected for analysis, manual extraction was chosen over the use of an API. As OpenSubtitles operates by user submissions, the quality of .SRT files can fluctuate in accuracy. The following criteria were used to select files, in order of priority: Sub Translator > Trusted > Administrator > Platinum Member > Gold Member > Silver Member > Bronze member > VIP member > Sub Leacher > anonymous. This procedure signifies that a file contributed by a Sub Translator was selected over an anonymous submission.

The construction and evaluation of our testing dataset resembles the approach used by Chen et al. (2020), yet it's tailored to our research context. We utilized a subset of the dataset provided by Pantula and Kuppasamy (2020), specifically focusing on films produced in spoken English with English subtitles. This subset includes binary readability ratings ('readable' labeled as 1 and 'highly readable' labeled as 2), converted from a 10-point Likert scale, with annotations gathered from university students in India, all non-native English speakers.

The original dataset by Pantula and Kuppasamy (2020) aimed to assess readability for a diverse set of low-literacy users, including individuals still developing their English proficiency, those with learning disabilities, and senior citizens. Our study, however, primarily concentrated on the English Language Learners (ELL) subgroup, consisting of university students with adequate L1 proficiency but for whom English is a second language. They evaluated films featuring spoken English dialogue and English subtitles, thereby providing valuable insights into this specific subset within the broader ELL spectrum.

The student evaluators considered various factors identified by Pantula and Kuppasamy (2020) that could influence readability, such as the reading rate versus speaking rate, pausing gaps while reading, and difficulties in interpreting captions' meaning. They also considered the timing of closed captions' appearance and disappearance in videos, which can impact user comprehension and reading speed.

**METHODS**

To determine the appropriateness of films for English Language Learners (ELLs), a comprehensive approach was adopted that included the application of a mix of traditional readability formulas, measures designed for ELLs, and a film-specific measure. A composite score was generated by combining the most effective features of readability found in the tested measures. The aim of this study is to compare the effectiveness of multiple readability formulas and modern measures in assessing film difficulty for ELLs, while also investigating the influence of additional factors in determining appropriateness for ELL viewers.
Traditional readability formulas are extracted using Python (Van Rossum & Fred, 2009) with custom scripts and the `Textstat` module (Aggarwal, n.d.) to generate values for equations 1-7. The complex score associated with the CEFR was generated through the CEFR checker web interface (McDowell & Settles, 2019). The Coh-Metrix L2 Readability Index (RDL2) was generated through the Coh-Metrix 3.0 web tool (McNamara et al., 2014).

The readability measures used here are traditionally associated with text complexity. To complement them, features specifically relating to video were devised for inclusion, namely the average number of words per second and word count over time. Here, words per second provides a generalization of the pacing of a film’s dialogue. This was accomplished with Python following procedures outlined by Onofrey (2019) which utilized the incorporated timestamp data aligned in the .SRT files.

To illustrate how accounting for the speed of dialogue of a film may benefit users and educators, a selection of five films differing in genre and production year are selected, including: *The Kid* (1921), *Aliens* (1986), *Baby Driver* (2017), *The Apartment* (1960), *His Girl Friday* (1940). Figure 1. demonstrates how a film like *His Girl Friday*, with over 3 words per second could elicit extraneous processing overload on an ELL of a lower proficiency. Similarly, Figure 2. provides an overall picture of the number of words expressed in a film over time.

Alongside testing specific existing readability measures, we aimed to investigate the particular features used in calculating these measures. With the emergence of new automated readability assessment methods and machine learning approaches, research suggests that blending these with traditional formulas can effectively assess difficulty levels (Liu et al., 2021). To this end, we implemented a stepwise feature selection using an ordinary least squares (OLS) regression model. This helped identify the most pertinent features and measures that could predict the target ELL score variable, based on the ratings given by English Language Learner students in the testing dataset. This iterative process eliminates the feature with the highest p-value, continuing until all remaining features have p-values below the chosen 0.05 threshold—indicating statistical significance.

The stepwise linear regression analysis identified nine readability features and measures that significantly contribute to predicting the target ELL score and to gauge film appropriateness for ELLs. These selected features include the number of sentences, words per sentence, Flesch Reading Ease, Flesch-Kincaid, Dale-Chall, Gunning Fog, Linsear Write, and the CEFR proportion of B1 words and B2 words. Each of these features has shown a statistically significant relationship with the target ELL score, indicating their importance in assessing film appropriateness for ELLs. The OLS regression model was fitted with the selected features, and the associated coefficients were obtained. These coefficients represent the estimated effect of each feature on the target ELL score while considering the other features in the model. A higher coefficient value suggests a stronger influence of the corresponding feature on the ELL score. By examining the coefficients, we can determine the relative importance of each feature in predicting the target ELL score and understanding their individual contributions to film appropriateness for ELLs.

The R-squared value obtained from the OLS regression model was 0.5791, indicating that approximately 57.91% of the variance in the target ELL score can be predicted from the selected features. This suggests that the chosen readability measures and features have a moderate explanatory power in predicting film appropriateness for ELLs. However, it is important to acknowledge that there may still be other factors not captured by these features that contribute to the remaining variance in the target ELL score. Further research and exploration are warranted to investigate these additional factors and enhance the predictive ability of the model.

From this, a composite score for the films was generated using the selected features associated coefficients in equation 9:
The use of sentence count as a variable for determining the difficulty of text has been extensively studied in the field of readability. This variable is commonly employed in traditional readability formulas, such as the Flesch Reading Ease and the Flesch-Kincaid formula, as a means of gauging derived features, such as the average number of words per sentence, in order to generate difficulty metrics. As such, this variable is consistently represented in all traditional readability formulas tested in this study. Furthermore, the continued relevance of this variable has been demonstrated in more sophisticated extracted features used in modern classification models for film, as evidenced by its application in assessing average sentence ambiguity in the work of Pantula and Kuppusamy (2020).

Both the Dale-Chall score and the proportion of CEFR B-level words represent measures of vocabulary difficulty in this study. The Dale-Chall score includes a variable based on the proportion of words that fall outside of the 3000 most commonly used English words, as identified by Dale and Chall (1948). In contrast, the B-level vocabulary metrics specifically focuses on the proportion of moderate-level vocabulary according to CEFR standards. While these measures are similar, they ultimately assess different aspects of vocabulary difficulty. By including both variables, we are able to achieve a more robust application of vocabulary difficulty as experienced by the tested ELLs. This aligns with previous research by Masrai (2019), which suggests that it is the combination and circumstance of high-, mid-, and low-frequency based levels of orthographic vocabulary knowledge as influential factors for L2 reading comprehension. In this sense, the Dale-Chall acts as a surrogate for the low-frequency words, while the B-level measurements are concerned with the higher and mid-frequency vocabulary distribution. The remaining features of the composite score, including the Flesch Reading Ease, Flesch-Kincaid, Gunning Fog, and Linsear Write, operate under the guise of a different form of lexical difficulty assessment by incorporating syllable count as a variable. In this sense, these measures are capturing a different component of expected word level difficulty compared to the Dale-Chall measure and B-level words.

The developed composite score used to evaluate the readability of film was applied to the dataset of the IMDB Top 250 English films. The results, presented in Table 2, demonstrate the top five films that were determined to be the most readable according to the composite score when in comparison to the other tested readability measures. In addition, Table 3 illustrates the films that were identified as the least readable, providing a comprehensive understanding of the relationship between the tested measures.

\[
\text{Composite Score} = 0.00067 \times \# \text{ of Sentences} \\
+ 20.39 \times \text{words per sentence} \\
- 12.29 \times \text{Flesch Reading Ease} \\
- 87.28 \times \text{Flesch-Kincaid} \\
- 0.50 \times \text{Dale-Chall} \\
- 0.79 \times \text{Gunning Fog} \\
+ 3.14 \times \text{Linsear Write} \\
- 22.78 \times B1 \text{ word} \\
- 11.54 \times B2 \text{ word}
\]

ANALYSIS
Research Question 1
To answer Research Question 1 we can direct our attention to Table 4 where results indicated strong to very strong correlations greater or equal to \( r (248) = 0.8, p<0.01 \), for the traditional readability formulas: Flesch Reading Ease, Gunning Fog, and Flesch-Kincaid, and ARI (Automated Reading Index). This can be attributed to the high degree of overlap between the specific variables found within these formulas. In many cases, such as the relationship between the Flesch Reading Ease and the Flesch-Kincaid grade level, a very similar calculation is performed. However, they differ in the regression analysis used to generate their respective formulas. Moderate to strong correlations were observed for the Linsear Write formula between \( r (248) = 0.6, p<0.01 \) and \( r (248) = 0.8, p<0.01 \) with traditional readability formulas: Flesch Reading Ease, Gunning Fog, Flesch-Kincaid, SMOG (Simple Measure of Gobbledygook), and ARI. A strong positive correlation \( r (248) = 0.84, p<0.01 \) was observed between Dale-Chall and the CEFR Complex Score. This can be attributed to the emphasis on variables engineered to assess difficult words. While Dale-Chall focuses on the percentage of words outside the most common 3000 words in English, the complex score focuses on the relative proportion of A1-C level words in a text excerpt.

Table 4. Correlation coefficients \( r \) for readability measures and mean inter-item correlation.

Notably the combination of percent difficult words of the Dale-Chall score and the moderately challenging B1 and B2 words proved informative for the generated composite score. This likely can be attributed to B level words providing a more in-depth understanding of the specific vocabulary found within a text. Moderate correlations are present for the Coh-Metrix RDL2 between \( r (248) = 0.5, p<0.01 \) and \( r (248) = 0.7, p<0.01 \) and readability measures: Flesch-Reading Ease, Gunning Fog, Flesch-Kincaid, Dale-Chall. To gain a better understanding of the relationship between measures, we opted for a mean correlation analysis of all measures signified in the last column of Table 4. Interestingly the two strongest correlations are the Flesch Reading Ease \( r=-.56 \) and the Coh-Metrix RDL2 \( r=-.37 \). It is important to note that the negative indicator here is only representative of the structure of these formulas where lower scores indicate increased difficulty, in contrast to the remaining measures. Further the complex score demonstrated the lowest mean correlation \( r=.12 \).

One of the potential benefits of applying readability scores to film recommendation for ELL is the breadth of films: it still allows for a participant to choose from a wide range of film types. To consider this benefit, we looked at the relationship between readability measures and critical consensus as well as genre. First, we measured the correlation between readability measures and a 100-point score from critical review aggregator Metacritic. The correlation was very weak, with an absolute \( r<=.06 \) for all measures except the CEFR Complex Score \( r=.15 \), suggesting that
readability scores do not discriminate between. Additionally, we evaluated the relationship between a readability measure (Coh-Metrix RDL2) and genre labels collected from Wikidata. Genre accounts for only 7.3% of the variation in the measure (F=1.889, p=.02).

**Research Question 2**
In order to address research question 2, a pointwise biserial correlation analysis was conducted to investigate the relationship between various readability measures and scores assigned by English Language Learners. Details of the analysis are shown in Table 5.

<table>

</tbody>
</table>

Table 5. Pointwise biserial correlation of ELL-rated film scores with existing readability measures and generated composite score. *p<.001

The results of the pointwise biserial correlation between the readability measures and English Language Learners' scores found in Table 5 suggest weak to moderate relationships. The Flesch Reading Ease, SMOG, and RDL2 measures showed correlation coefficients of -0.17, 0.15, and 0.22, respectively. The composite score calculated showed the strongest relationship, with a moderate to strong correlation coefficient of $r_{pb} = 0.76$ ($p < 0.001$). It's important to note that the small sample size of 36 may have limited the power to detect significant relationships. Despite this, the results suggest that the composite score may be a useful tool for predicting the difficulty of film subtitles for English Language Learners. The findings indicate that while the individual variables associated with the readability measures have some influence on the difficulty level of film media, certain measures are more suitable than others for this particular type of media. Interestingly, the average words per second, used to reflect the relative dialogue speed of the film, showed the least correlation with audience level scores, tying with the ARI score at $r_{pb} = 0.06$. Perhaps this relates to the parameters applied to participants for the construction of the testing dataset. Further research is needed to confirm these findings and to establish the most appropriate measure of readability for film media.

**DISCUSSION**
This initial exploration provides valuable insight into the relationship between various readability measures and their application when assessing film difficulty for English Language Learners (ELLs). The results of the study indicate that there is a strong internal consistency between traditional readability formulas which can be attributed to the feature overlap in their respective calculations. Additionally, the results show a strong relationship between the CEFR Complex score and the Dale-Chall readability formula. This can be ascribed to the fact that both calculations place a specific emphasis on vocabulary difficulty. Furthermore, the results showed that none of the individual measurements tested yielded highly definitive results in determining the difficulty of films for English Language Learners (ELLs). However, the combination of raw variables from traditional formulas and the integration of modern measures as features was found to be more effective in assessing the difficulty for ELLs.

This research is an important step in understanding how readability measures can be used to assess film difficulty for ELLs and provides a foundation for future research in this area. The opportunity to adopt automated methods of assessing content difficulty with readability measures for ELLs is an achievable and a feasible option for libraries. Although, defining the best method or measure to implement for library holding metadata is something that needs to be further considered. It is relevant to note that traditional and modern measures are constrained in both the features that are being assessed and the target population being served. For example, traditional formulas were largely
This study aimed to explore the use of readability measures on film text data to enhance library resources for educators and ultimately may be a more appropriate solution for enriching library metadata for ELLs. A comparative analysis was conducted to examine the relationship between different readability measures. To examine the correlation between readability measures and perceived difficulty for ELLs, a composite score was developed by incorporating relevant variables. Results from a pointwise biserial correlation analysis indicate that a combination of variables from traditional formulas and modern measures specifically designed for ELLs demonstrated the strongest correlation with perceived ELL difficulty. Furthermore, the study offers suggestions for improving the assessment of ELL difficulty by incorporating personalized components, such as user-specific aspirations relating to English variety and register.

CONCLUSION
This study aimed to explore the use of readability measures on film text data to enhance library resources for English Language Learners (ELLs). A comparative analysis was conducted to examine the relationship between different readability measures. To examine the correlation between readability measures and perceived difficulty for ELLs, a composite score was developed by incorporating relevant variables. Results from a pointwise biserial correlation analysis indicate that a combination of variables from traditional formulas and modern measures specifically designed for ELLs demonstrated the strongest correlation with perceived ELL difficulty. Furthermore, the study offers suggestions for improving the assessment of ELL difficulty by incorporating personalized components, such as user-specific aspirations relating to English variety and register.

ABSTRACT
Digital, community-based knowledge infrastructures confront complex, systemic challenges to their sustainability over time. From digital community archives to computationally amenable corpora, databases, or data models created by and serving research communities, these sites of grassroots knowledge production tend to be maintained without long-term institutional commitments. Yet, they hold unique cultural evidence of enormous value. Prior work on the sustainability of digital humanities scholarship has surfaced numerous factors in project sustainability, including technical, organizational, and financial concerns. The roles of communities themselves in sustaining community-based knowledge infrastructures, however, are under-studied. This qualitative, multi-case study of digital humanities projects and digital community archives addresses community-centered approaches to understanding and implementing sustainability for digital knowledge infrastructures. This study finds that communities of various kinds—from public communities to networks of research practice—conceive of the sustainability of their digital projects as inextricably linked to the sustainability of communities themselves. We offer an exploration of factors in the mutual relationship of sustainability between communities and their knowledge infrastructures, including how they support the wellbeing of individuals and cohesion among communities, and how they promote activism and advocacy efforts within broader publics and disciplinary cultures.

KEYWORDS
Digital archives; digital humanities; sustainability; digital preservation

INTRODUCTION
Community-based, digital knowledge infrastructures—including digital community archives and many digital humanities projects—are notoriously difficult to sustain over time (Zavala et al., 2017; Smithies et al., 2019; Edmond & Morselli, 2020; Drucker, 2021; Maron & Pickle, 2014). They tend to be maintained by small teams of volunteers and rely on short-term funding and fragile technical infrastructures (Fenlon, 2020). Digital humanities projects that are based in academic or cultural institutions—but which involve grassroots digital curation efforts or collaborations with trans-institutional communities of research and practice—confront similar sustainability challenges to digital community archives belonging to groups unified by shared identity, memory, or place. These are all sites of digital, cultural knowledge production, and they exist on a spectrum of shifting community and institutional support. They are community-centered, in the sense that they are intended to serve the immediate research needs or values of the public and academic teams and wider groups that collaboratively build, maintain, and use them. They tend to operate outside of, or otherwise defy, the paradigm of institutional stewardship that protects the mainstream cultural record in libraries, archives, and museums.

At the same time, community-based, digital knowledge infrastructures often collect and maintain invaluable evidence—and innovative interpretive or secondary work—focused on peoples, histories, languages, and cultural phenomena that may not be well documented or accurately represented in mainstream memory institutions. Digital community archives and digital humanities projects often represent the histories and cultures of marginalized groups, with the goal of rebalancing the equity and inclusivity of the cultural record in such a way that keeps stories and knowledge under the control and power of community ownership. These factors make digital, community-based projects simultaneously invaluable as sites of grassroots knowledge production, and at the same time highly vulnerable to loss.

Our research considers the urgent question of how to improve sustainability for digital, community-based projects in ways that are truly community-centered. Community-centered sustainability approaches take community ownership and power meaningfully into account, and do not rely exclusively on the conventional approach of handing off ownership of primary sources or digital artifacts to institutional preservation, but instead seek to maintain digital projects and their outcomes over the long term as living, vital, community-owned resources (Fenlon et al., 2021; Fenlon & Muñoz, 2019).

Through a comparative, multi-case study of four digital humanities projects of different kinds, we have addressed the question of how different communities understand and implement sustainability for their digital collections. Our qualitative case studies included a total of 44 semi-structured interviews, along with participant-observation and...
analysis of documentary evidence, to characterize how communities contribute to the sustainability of their own digital knowledge infrastructures. We restrict our analysis in this paper to a subset of three out of our four cases, due to space limitations, and therefore include a total of 34 interviews in the reported analysis. The digital resources at the center of each case study include a digital archive, a machine-actionable corpus of texts, and a community-maintained data model. Each of these resources are created by relatively small core teams, but these teams and the resources themselves are surrounded, supported, used, and sustained by wider communities as well, which range from local communities to networks of collaborative research or groups joined around shared digital methodologies. Through this research, we have identified a framework of factors in the community-centered sustainability of digital humanities projects, including digital community archives (Fenlon et al., 2022).

This paper reports on select findings of this study, specifically related to one factor: the mutual relationship between the sustainability of digital knowledge infrastructures and the sustainability of the communities that create and maintain them. How do digital, community-based projects contribute to the wellbeing and endurance of communities themselves? In prior work, which reported a preliminary analysis of a single case study, we observed how one digital community archive serves its community by enhancing social ties as a hub for collaborative effort, and by helping to catalyze activism and advocacy efforts for the community (Fenlon et al., 2021)—outcomes which resonate with the broader literature on community archives as activist spaces, which also support community wellbeing (Treloyn and Emberly, 2013; Cifor et al., 2018; Caswell et al., 2018; Stevens et al., 2010; Flinn et al., 2009). This paper builds on our previous work by examining a fuller set of case studies.

Our central finding is that our communities conceive of the sustainability of their digital projects as inextricably linked to the sustainability of communities themselves. The wellbeing of communities is understood to have a mutual or reciprocal relationship with the digital knowledge infrastructures the communities create and maintain—each serving the endurance of the other in nuanced and context-specific ways. In this paper, we explore those nuances, including how community-based digital knowledge infrastructures support career advancement for participants in communities, help to diversify disciplines and engage broader communities in projects, maintain social cohesion among communities, contribute to improving disciplinary cultures, and promote activism and advocacy efforts.

**PRIOR WORK**

Community-based digital cultural knowledge infrastructures are notoriously difficult to sustain (Fenlon, 2020; Zavala et al., 2017; Smithies et al., 2019; Edmond & Morselli, 2020; Drucker, 2021; Maron & Pickle, 2014). Many digital humanities projects and digital community archives meet this description, which adapts Edwards’ (2010) definition of knowledge infrastructures as “networks of people, artifacts, and institutions that generate, share, and maintain specific knowledge” (p. 17), to focus on the community-based production and maintenance of cultural knowledge in digital forms. Such efforts tend to rely on short-term models of funding as well as bespoke technical architectures, which are prone to breakage. They operate under resource constraints and tend to rely heavily on volunteer labor. Even where projects or their members carry some level of institutional affiliation, as is the case for many DH projects that originate in the academy, those affiliations rarely bring along an institutional commitment to a project or any promise of support over time. Indeed, many academics, including humanities faculty and librarians, work on DH projects in the margins of their time or without significant opportunity for credit or reward for their labor (Pilsch & Ross, 2022; Risam & Edwards, 2018). The curatorial work behind the scenes of DH projects, before they reach the point of publication, is often described as “invisible labor” (e.g., Graban et al., 2013; Klein, 2020), drawing on a concept stemming from feminist labor studies to characterize certain genres of digital work that do not garner recognition or valorization because they take place largely out of sight—of administrators, of funders, of evaluators, or of the marketplace (e.g., Klein, 2020). The invisibility and lack of recognition and reward for DH work within the academy continues to be amplified when projects are public-facing or community-based (Burton et al., 2021), despite what seems to be a paradigmatic turn in this direction in recent years. Outside of academic and cultural institutions, within digital community archives, some of these issues can be compounded: there are, of course, fewer mechanisms for extrinsic compensation or reward, fewer opportunities for using shared infrastructure, and less access to the technical expertise needed to effectively develop and maintain digital projects (Newman, 2011; Froese-Stoddard, 2014; Lian & Oliver, 2018).

In digital curation and digital humanities broadly, there is little consensus on what sustainability means or entails (Eschenfelder, 2016; Drucker, 2021). This is, in part, because sustainability is a complex concept, which has been redefined in every scholarly context and discipline that deploys it, and which is highly subjective and difficult to operationalize (Bell & Morse, 2008). In this paper we define sustainability as the endurability of digital projects as changeable, community-based resources in active use, and responsively serving community needs. From this perspective, the concept of sustainability is distinguished from that of digital preservation by its emphasis on maintaining living, evolving digital resources within their native contexts, rather than archiving static representations within dedicated systems of stewardship. Despite some overlap in pragmatic approaches to
sustainability and digital preservation—particularly when we consider the sustainability of primarily digital artifacts and objects—the digital humanities literature acknowledges the distinctions between these concepts (e.g., Miller & Taylor-Poleskey, 2020; Kilbride, 2015).

Research on improving sustainability for community-based digital projects has become a priority over the past few years as DH practitioners, funders, administrators, and other stakeholders explore remodeling systems of labor and credit, identify alternative funding models for community archives (e.g., Jules, 2019), and explore the constraints and possibilities of shared infrastructures. Yet, the problem remains largely intractable, in part for lack of recognition of certain key factors in DH and community archives sustainability. The prior empirical work on sustainability in the DH literature focuses predominantly on two core facets of sustainability for digital scholarship:

- The long-term viability of technical artifacts and infrastructures: Approaches to this focus on digital preservation and curation practices (e.g., Goddard & Seeman, 2019; Miller & Taylor-Poleskey, 2020; Kilbride, 2015; Poole, 2015), building shared technical infrastructures (e.g., Blanke et al., 2017; Dombrowski, 2014), and partnering with curation institutions to preserve projects (e.g., Sweeney et al., 2017; Vandegrift & Varner, 2013; Clement et al., 2013; and Pool & Garwood, 2020).

- The financial and management aspects of sustaining organizations, units, and projects: Approaches to these focus on business models and strategies for management, staffing, and governance (e.g., Zorich, 2008; Maron et al., 2009; Steurmer & Abu-Tayeh, 2016; Pratono et al., 2020), and building institutional partnership networks (e.g., Almas, 2017; Spiro et al., 2017).

While this rich literature has made significant headway on a subset of the facets that contribute to the sustainability of community-based digital knowledge infrastructures, it tends to obscure or overlook the critical roles of communities themselves, which are more nebulous entities that transcend teams and organizations. A smaller body of work has explored the impact of communities and community-based strategies in DH sustainability (e.g., Smithies et al., 2019; Langmead et al., 2018; Warwick et al., 2008). In particular, Edmond and Morselli (2020) offer a similar division of the prior DH literature in this area into two main categories of metaphors guiding sustainability planning: (a) sustainability as data preservation and the technical robustness of tools, versus (b) sustainability as the maintenance of organizations or institutions. They offer an additional category: sustainability as a user issue, which resonates with our conception of community-centered sustainability. Work in this vein considers how community needs factor into sustainability planning (e.g., Edmond Morselli, 2020; Smithies et al., 2019; Langmead et al., 2018; Warwick et al., 2008); how communities can form supportive networks (e.g., Edmond, 2013; Blanke et al., 2017); and community-building practices (e.g., Skinner, 2018; Arthur, 2014; Clement et al., 2013). This last body work often focuses on user communities, rather than assuming a broader perspective on potentially invested and allied groups. There is a distinct need for empirical research on community-centered sustainability approaches for DH and digital community archives. Community-centered approaches prioritize community needs and values in how they define and approach sustainability, rather than the pragmatic needs or workflows of organizations and institutions under the contemporary paradigm of library stewardship. In addition, a community-focused conceptualization of sustainability focuses on the roles that different groups play in sustaining digital projects and collections, as a complement to the necessary factors of financial, technical, and organizational pillars of support.

CASES

This paper reports on a subset of a multi-case study of four digital humanities projects. However, in this paper we restrict our analysis to the following three cases, in light of space constraints. While all are being developed by specific groups as new knowledge infrastructures, to meet their particular research needs, they differ in key dimensions that are relevant to sustainability—such as in topicality or domain, size and scope, stage of development, institutional support, and funding history. These cases were also selected to leverage proximity and prior connections between the PI and case study projects, as this is a time-constrained study and our participant-observation methods relied on relationships of connection and trust between partners and the research team, building which requires significant time and effort. Here we briefly characterize the core teams and communities involved in each case. The types of communities are different in each case, and projects are “community-centered” to varying degrees. A fuller description of the communities in each case and the relationships among them is available in Fenlon et al., 2022.

Lakeland Digital Archive

The Lakeland Digital Archive is the community archive of a 130-year-old African American community in College Park, Maryland, adjacent to the University of Maryland (UMD) near Washington, D.C. Lakeland thrived for decades before the process of urban renewal demolished much of its landscape and displaced two-thirds of residents from their homes. For more than a decade, Lakelanders—including historical and current residents and their descendants—have worked to collect and preserve the community’s story, to document its contributions to regional history, and to advance the interests of the surviving community and present-day Lakeland residents. The Lakeland
Community Heritage Project (LCHP), a small, volunteer-run organization, has partnered with UMD faculty and the Maryland Institute for Technology in the Humanities (MITH) to prototype a new, digital community archive. The beta version of the archive, now online, holds 4,000+ digital objects. LCHP’s efforts have given rise to a restorative justice initiative, and the City of College Park’s Restorative Justice Steering Committee is exploring reparations for the Lakeland community in light of the harms done during urban renewal, making College Park one of the first cities in the country to take action on reparations specifically related to the legacies of urban renewal (Bernard, 2021). Relevant and invested communities include not only Lakeland but other historically connected, regional communities, the UMD community, and peer community archives.

**Music Encoding Initiative**

The Music Encoding Initiative (MEI) is an effort led by a combination of scholars, volunteers, and practitioners working within the field of musical research. MEI utilizes open-source technologies to encode musical documents into a machine-readable structure, to support digital representations and analysis. Invested groups include librarians, historians, theorists, and developers. One of MEI’s major products includes the MEI schema, which provides a core set of rules for recording physical and intellectual characteristics of music notation documents expressed in XML. In addition to the MEI Schema, the initiative provides the MEI Guidelines, which explain the MEI model and its suggested best practices. The MEI community’s governing body, comprising an elected board and technical team, oversee maintenance of MEI's GitHub repository and release updates. In addition, several interest groups focusing on specific areas of development, such as pedagogy, metadata, and musical notation, drive most of the activity and continuous development of the standard. Despite being a relatively small group of volunteers from the academic musical community, consisting of scholars and librarians, they serve as a hub for a broader community of users, conference attendees, and participants in the community’s online forums, including a listserv and Slack space.

**Open Islamicate Texts Initiative and KITAB project**

The Open Islamicate Texts Initiative (OpenITI) is a cross-institutional endeavor to create a machine-actionable corpus of premodern Islamicate texts and tools for textual analysis for Arabic, New Persian, Ottoman Turkish, Urdu, and other Islamicate languages. The closely related Knowledge, Information Technology, & the Arabic Book (KITAB) project aims to provide scholars with new tools for textual analysis. These projects form part of a cluster of interrelated strands of research involving a constellation of overlapping collaborators. These initiatives also invite participation and contribution from scholars across history and other humanities subdisciplines, as well as natural language processing. Relevant groups and communities include individuals providing textual data, developers interested in optical character recognition and handwritten text recognition techniques, historians studying Islamicate texts, teachers looking to utilize texts in their work, and potentially more general readers of Arabic and Persian texts.

**METHODS**

This case was designed as a multiple-case study (Yin, 2018) of four digital humanities projects, with the objective of characterizing the relationship between communities and the sustainability of digital humanities projects, including digital community archives. In this paper, we report selected findings from only three of the four case studies, as including all four would exceed our space constraints. The use of a multiple-case study as our method supports the dual goals of (a) replication of findings about factors that lend to community-centered sustainability, and (b) cross-case analysis of expected contrasts in how different communities conceptualize sustainability and implement sustainability strategies. Our data collection and analysis protocols were guided by two main theoretical propositions, derived from a review of prior work on sustainability in the digital humanities and community archives literatures: (a) Digital humanities projects are surrounded and supported by communities of different shapes, scopes, and sizes, which play various, vitally important roles in sustaining those projects; and (b) The meaning and entailments of sustainability vary significantly depending on context.

The unit of analysis in each case was a digital humanities project, including its associated core team and wider communities. Data collection and analysis encompassed semi-structured interviews, participant observation, and analysis of documentary evidence associated with each case, including digital resources produced by the projects, various channels of communication for the team(s) and communities surrounding each project, the websites and grant narratives associated with each, technical documentation, etc. Data collection and analysis for all cases were conducted from the fall 2019 through spring 2022. Table 1 provides an overview of the sources of evidence used in each case. Cases varied in size and scope, and in the depth of our participant-observation work.
This paper reports on results of a subset of 34 interviews conducted across three cases. This is a subset of our full data collection, which includes 44 interviews across four cases; but reporting on the fuller analysis is out of scope for this paper. Following IRB approval and consenting processes, we conducted semi-structured interviews with a majority of core team members involved in each case, as well as representatives from wider invested communities. Each interview lasted approximately an hour and was done either via Zoom video call or in person (until the beginning of the COVID-19 pandemic, at which point all interviews and most participant-observation work happened via Zoom video calls). Interviews were transcribed using Otter.ai transcription software, and manually edited for accuracy, before we subjected them to qualitative content analysis (Zhang & Wildemuth, 2016) to identify relevant themes in each interview with supporting quotations. To support this analysis, we used Atlas.ti qualitative coding software. Our codebook was created in part deductively, based on the theoretical propositions with which we began, but many of our codes derived inductively from analysis of the data itself, arising from new and unexpected insights from participants or themes and patterns in their interviews. As we conducted analysis we adjusted and refined the codebook to reflect our growing understanding of the patterns and themes we were seeing across cases, and re-coded iteratively as needed. At least two coders independently coded every interview. The coders then met to discuss their codings and to achieve consensus on the codings, to achieve total interrater agreement (rather than meeting a statistical threshold of interrater reliability) (Zhang & Wildemuth, 2016). We first analyzed data from each case independently, and then sought to draw cross-case conclusions. We offered case study partners the opportunity to review our preliminary findings and refined our analysis based on their feedback. Case study partners are also invited to review all publications associated with this work.

The communities represented in our cases, of course, are not monolithic. There was no firm consensus among community members about what sustainability means or entails for their digital projects, so in the findings below we aim to reflect the diversity of their responses and perspectives. We use alphanumeric participant identifiers to distinguish participants when quoting them, wherein the first letter of the identifier refers to the relevant case study (LXX for Lakeland participants, MXX for MEI participants, and IXX for OpenITI/KITAB participants).

**Limitations**

Our level of engagement with each case study varied due to contextual factors—how busy our case study partners were, how well the timing of our research coincided with their own timelines, the physical locations of our partners and whether there were clear inroads for investigator participation in each project. Variation in the level of engagement across cases is to be expected, and we have worked to reflect on how our varying levels of engagement affected our interpretation through our memoing processes. We also rely on evaluation by our case study partners to help confirm our understanding of each case.

While they exhibit many important and useful differences for the purposes of understanding the roles of communities of varying disciplines, shapes, sizes, and with varying intellectual and social objectives, our cases

**Table 1. Data sources across three cases**
proved to be homogenous in certain ways that limit our capacity for analytic generalization (Yin, 2018). Our cases do not include any projects without prior funding, or any projects that are completely independent of institutional affiliations. (In fact, three out of four of our cases have significant attachments to the University of Maryland, as described above). While further cases to probe these facets—of funding history and institutional affiliation—are out of scope for this study, we hope to come back to these important facets in future work.

**FINDINGS**

While we found significant variation among the kinds of communities involved in each case and their levels of investment, in every case participants perceived their core teams and their emergent knowledge infrastructures to be serving a broader set of groups of shared interest, who are either actively or potentially involved in each project and its sustainability over time. Figure 1 offers an abstract view of how communities surround the core teams involved in each case. This is a rough and generalized depiction, derived from more detailed and case-specific illustrations offered in Fenlon et al., 2022. The goal is to illustrate how different types of communities radiate outward in metaphorical distance, or level of active involvement, from the center of each project. In every case the center constitutes a small, core team of volunteers. Beyond this team, participants perceived a variety of groups ranging on a spectrum from closest to furthest involvement in the active maintenance and development of each project, from being core partners, to contributors, to users, to potential allies whose involvement is latent but potentially beneficial to each project’s sustainability. Each general category depicted was described by one or more participants as having immediate or potentially useful roles to play in the sustainability of the project.

![Figure 1. Characterizing the types of groups and communities that surround each case study core team](image.jpg)

The most significant outcome of this work pertains to how participants in each case define sustainability in the context of the various communities they identified. Critically, participants across all cases tended to understand sustainability as manifesting not only through durable digital resources or financially stable and consistently staffed projects, but also through direct and indirect benefits to the wellbeing and sustainability of the core communities surrounding each project. In other words, they understood their projects to be sustainable if and only if their projects were actively contributing to the sustainability of their communities in various ways. In this section we explore the dimensions of this perceived mutual relationship between the sustainability of communities and their community-maintained knowledge infrastructures.

The principal benefit of a community-generated knowledge infrastructure for its community, in every case, was the most intuitive: to serve the purpose for which it was built, which reflects an immediate need among participants in the project and wider, related communities. In Lakeland’s case, the most immediate factor in how the digital archive supports the Lakeland community is in how it preserves the community’s valuable story from obscurity. In MEI’s case, the data model serves the community most directly by opening novel avenues of research, musical representation, and engagement. In the case of OpenITI and KITAB, the immediate purpose is to build digital tools and textual resources, which will provide broader access to Islamicate texts and enable computational and cross-language analysis of texts that have been historically inaccessible to relevant fields of research.
Beyond these immediate benefits to communities, our findings below highlight more nuanced ways in which the digital projects and resulting knowledge infrastructures support community wellbeing, by helping to build communities and increase social cohesion, by confronting issues of labor and credit that stymie fieldwide sustainability, and by promoting various advocacy and activism efforts.

**Sustainability as community and individual wellbeing**

For participants across projects, discussions about project sustainability often began with the maintenance and preservation of technical infrastructures or digital objects, but in every case the focus of the discussion rapidly shifted to the long-term wellbeing of the community itself, or individuals within the community. Participants were noticeably less concerned with the longevity of project artifacts or infrastructures—or even with the viability over time of specific constellations of people, funding, and technical resources that define “projects”—than with the human outcomes of their work. Participants defined the sustainability of their efforts as being realized through the wellbeing or sustainability of their communities, or of individuals within those communities. We originally identified this trend within the Lakeland case (Fenlon et al., 2021), where this sustainability imperative aligned closely with the impetus for the project as a whole—to maintain a community’s memory and impact. Our subsequent cross-case analysis has confirmed the pattern across cases, and it is striking to see this manifest among teams and communities defined around shared research rather than shared memory, where interpersonal commitments might be less intuitive or strong.

**Building community**

In the OpenITI and KITAB projects, for example, one participant characterized what they hope to sustain beyond the life of the project as an emergent network of collaborators with shared interests that exceed the boundaries of their current projects: “what we’re hoping to build is a network of people that will outlive the very specific formulation that is these funded projects” (I03). Multiple participants described how the network of collaborators on the OpenITI, KITAB, and related projects emerged from overlapping but distinct research interests: while all were invested in computational methods, and in different aspects of medieval history and literature, which cross linguistic boundaries: “we really have a common interest in joining together, developing standards together, developing infrastructure” (I02). The object of sustainability transcends the project’s intended deliverables—of a technical infrastructure comprising a digital corpus and analytic tools—to encompass social aspects. A participant described the emerging, sociotechnical research infrastructure as being built through “common webs of collaborations. And the corpus is the place we meet” (I03). From this perspective, the corpus—the ostensible main objective of the project and collaborations—is not the singular sustainability concern. Nor are the constellations of specific resources, people, and objectives that define the current cluster of projects. Instead, the corpus is positioned as a functional hub for an emergent, enduring collaborative network, which is the actual object of sustainability.

Sustainability for this collaborative network, in turn, depends in part on other social factors: drawing in new collaborators, and ensuring job stability for vulnerable members of the team. OpenITI and KITAB participants described the importance of expanding the communities invested in the project. Some participants talked about the strategy of involving the technical resources in classroom education, or hosting training workshops, as a way of broadening the user base (I01). Others talked about making the resource or the collaborative development process itself more inclusive—to reach people studying topics of tangential interest across related cultures or languages, such as researchers of the premodern Islamic world, of modern Islamic literature (I02), or African Sufism (I05); to engage broader publics of readers (I05); and to involve other projects doing more niche corpus-development work (I02). Participants were not unanimous about what the scope of the OpenITI and KITAB communities or audiences should be, whether in the project’s current stage or in the future.

**Labor and credit**

The other aspect of sustainability for a collaborative network stemming from the OpenITI and KITAB projects pertains to the careers of individuals within the network. Participants placed emphasis on the vulnerability of early-career members of the team, including graduate students and postdoctoral scholars as all of these projects are set against a broader backdrop of resource-scarcity in the humanities, including a dearth of full-time, permanent academic jobs in the humanities. Beyond ensuring that the data are accessible, graduate students and postdoctoral scholars associated with the project need tangible recognition for their intellectual contributions to collaborative work, to get credit toward career advancement: “sustainability requires probably both of those—making sure all the data is accessible…and then under that, too, is that those who are contributing to it are recognized for that” (I03). This is not a simple matter, as multiple participants recognized, both within the OpenITI case and the MEI case, that collaborative, digital scholarship is rarely rewarded or fully credited by traditional mechanisms of academic evaluation, which favors traditional modes of scholarship. As the same participant described of their graduate students and postdoctoral scholars, “I powerfully want to advocate for them, so they individually end up doing really well out of this…. [but] the bottom line is, they can't create resources for other people. They can do that. Sorry, but they can’t only do that” (I03).
In the MEI community, too, participants pointed to the career impacts of involvement in the MEI effort as a key factor in the sustainability of the community and the standard in turn. The MEI community provides new opportunities for member-participants, but also illustrates how disciplines continue to devalue digital scholarship, which makes involvement risky especially for early-career scholars without stable, long-term positions. Still, the reluctance of the musicology field, particularly in North America, to give due credit for digital scholarship, by compensating or rewarding individuals creating digital projects or contributing to their upkeep, poses real challenges to individual community members and the sustainability of the community as a whole. Several interviewees touched on this subject, one pointing out that “the community members are the engine or the drivers of this sustainability of the standard itself” (M15), and another explaining that “people are still a little bit reluctant” to embrace MEI or digital methods more broadly. Several participants recognized that, for this reason in part, much of the work falls upon a small number of people, which is in itself a sustainability risk. As one participant noted, “it’s not a really big community … the active ones. If you go to the different interest group meetings, you don’t have thousands of people there … and you don’t have dozens” (M11).

**Maintenance of social ties through process vs. product**

The intertwined relationship between the sustainability of the research communities and their knowledge infrastructures parallels what we found in the Lakeland case, which is centered in a different kind of community. Lakelanders are unified around shared identity, history, and memory—as opposed to a community or network of practice formed around intersecting research topics and shared research infrastructure, as in the other cases. In Lakeland, as previously reported in Fenlon et al., 2021, the core conception of sustainability for the community archive is inextricable from the wellbeing of the community itself. The maintenance of social ties within the community, despite its ongoing experience of diaspora, is one of the core objectives of the archive. Indeed, the processes of the archive’s development—as much as the product of the archive itself—serve the function of social maintenance, and therefore define sustainability for the archive. As one participant noted, it “wasn’t just about an archive. It was about a whole bunch of people relating around the archive and the organization of LCHP itself” (L02). The archive also plays a role in generating awareness and political goodwill for the community, by documenting the community’s importance to regional history, as a “hotspot of African American history” (L06). Furthermore, the Lakeland community understands the archive to advance the wellbeing of the community—including historic and current residents and descendants, and even people with shared aspects of identity in the local area or Black students at the adjacent university—in direct, active ways, as discussed below.

**Advocacy, activism, and social change**

Our cases also see their digital knowledge infrastructures as participants in direct and indirect efforts toward activism or advocacy for positive, sociopolitical and disciplinary change. In Lakeland’s case, the effort has helped catalyze a restorative justice initiative for the historic community, and participants see the archive as useful for guiding active urban development planning efforts. In the other two cases, the digital infrastructures are understood to be participating in intentional but more gradual efforts to influence broader disciplinary cultures, by diversifying disciplines and advancing the uptake of digital methods.

In prior work, we described how participants saw the value of the Lakeland Digital Archive for informing present-day development decisions related to transportation, zoning, and land use, as the archive documents this historically harmful effects of the creation physical barriers such as high-rise architecture and train tracks that divided and separated the community from nearby neighborhoods and local amenities (Fenlon et al., 2021). Multiple participants sought to bring the archive’s stories to bear on ongoing city strategic planning initiatives. Participants acknowledged, however, that leveraging the archive for political purposes carried attendant risks to its sustainability—by inviting political opposition or subjecting the archive to the wax-and-wane cycle of broader political interest (Fenlon et al., 2021). The social justice impacts of the archive have since progressed from advocacy to an active restorative justice initiative.

Participants understand the archive to be a catalyst for an emergent restorative justice initiative, which has been taken up by the City of College Park. Participants saw the archive—and particularly the collaborative energy and momentum built around it—as key factors in drawing attention to Lakeland’s story and motivating a response from actors and institutions that played active or passive roles in the destruction of the Lakeland community. While acknowledging that the restorative justice initiative had not yet borne out in tangible reparative benefits for the Lakeland community, one participant related the archive to maintaining attention at a critical juncture in the process, “from the current state where there’s a commission looking into making recommendations…to an actual restorative justice process” (L12). For most participants, the activist effects of the archive were not necessarily perceived to be the original or core objectives, but were a secondary, welcome outcome. The archive “widens the table for the City to come to” in negotiations about restorative justice (L06). Multiple participants, in fact, saw the restorative justice initiative as feeding back into the sustainability of the archive itself: “When we talk about reparations, we can
discuss ways to improve the archive. It’s not just opening your checkbook, it’s promises that can be made to ensure the sustainability of our documentation, heritage, and culture” (L06).

**Advocating for disciplinary change**

In our more academic cases, the advocacy work underway through the community-based knowledge infrastructures targets disciplinary cultures rather than public communities and governing bodies. In MEI, this work is focused on diversifying the discipline and increasing the recognition and acceptance of digital methods. In OpenITI, too, the focus is on increasing the recognition and valorization of computation work within relevant humanistic disciplines.

Several participants cited the increasing work of MEI to diversify the groups of people and types of music they support as a source of sustainability for the project and the community as a whole—by opening gateways to new communities while broadening the individuals contributing to the project, noting the symbiotic relationship of the contributors and benefactors. One participant noted, “we're moving more to geographically diverse, as well as … racially and ethnically, but it's slow, right? I think it's because it's such a niche thing” (M05). The goal is to diversify the types of music capable of representation in the MEI data model, and to simultaneously open the community itself to broader participation, internationally and demographically. MEI projects, created by community members, provide new and nearly always open access means by which to study scores and musical compositions individually or at the corpus level, making new methods of study available to a wider range of graduate students. A consistent group of committed members, many of whom serve on the technical committee, put on regular “intro to MEI” workshops at conferences, and contribute to tutorials on the MEI website to facilitate asynchronous learning of the basic tenets. The pedagogy group furthers these causes by creating materials and space for educators to incorporate MEI into their classrooms. They also frequently present at conferences to spread awareness of opportunities for engaging students with MEI and promoting it as a transferable skill. Further, the organization also provides subsidies for their travel to conferences and have continued the pandemic practice of online and now hybrid conferences as a means of increasing accessibility and diversity. To increase the use and standardization of MEI as a preservation and encoding standard, the metadata interest group often provides feedback and answers for librarians and archivists who use MEI in their work. Its proliferation in this space saw it recently added to the Library of Congress’s preferred digital formats, which will increase the number or works in this format that they collect and continue to validate the use of the standard, for both academic and preservation and access purposes.

Participants in both the MEI and OpenITI/KITAB case studies described working despite and against the resistance of disciplinary traditions, as mentioned above in our discussion of labor and visibility as factors in the sustainability of both communities. In OpenITI and KITAB, participants considered how their projects contributed to broader trends in the humanities, including incremental progress toward integrating digital methods into disciplinary cultures. One participant acknowledged that this work confronts “a longstanding issue that’s bigger than the OpenITI or KITAB project”, of barriers not only between digital humanists and people deploying traditional humanistic methods, but also within the digital humanities, “a rigidity in thinking…about what is important to look for”, or what kinds of analytic work have merit (I05). Their hope for the sustainability of these projects was to influence disciplinary cultures towards advancement past such divides, and to help foster common vocabularies among disparate researchers working on shared problems.

**DISCUSSION AND CONCLUSION**

In this paper we have explored the nuanced ways in which the digital cultural knowledge infrastructures support community wellbeing, by helping to build communities and increase social cohesion, by confronting issues of labor and credit that stymie fieldwide sustainability, and by promoting various advocacy and activism efforts. Figure 2 synthesizes our findings on the reciprocity between the sustainability of communities and the digital knowledge infrastructures that they create and maintain.
This synthesis focuses specifically on community-related factors in digital project sustainability. Clearly there are a plethora of other critical factors that affect the long-term viability of projects and digital resources, including financial factors, management and organizational factors, staffing, etc. The table omits the acknowledged tradeoffs or risks of these factors, which do not have exclusively positive effects on community wellbeing. For example, participation in these kinds of digital projects can result in unrecognized and unrewarded labor for vulnerable early-career scholars; and the activism of a digital archive may invite unwanted visibility or political opposition.

However, our findings shed new light on how we can reverse our approach to sustaining digital scholarship and digital community archives: from one that prioritizes the endurance of digital resources or formal organizations, to one that puts communities first, and considers how community-based digital knowledge infrastructures sustain communities themselves. Our findings also affirm that sustainability is a distinctively sociotechnical phenomenon, one that will not have exclusively financial or technical solutions, but which must fall back on the complex and shifting landscape of nebulous social groupings that surround, support, and use digital projects.

While prior work on community archives and public-facing digital humanities scholarship has emphasized the importance of such efforts for advancing the social justice causes of communities (Treloyn and Emberly, 2013; Cifor et al., 2018; Caswell et al., 2018; Stevens et al., 2010; Flinn et al., 2009), our findings shed light on additional ways in which a variety of community-based projects, as collaborative sites of knowledge production that engage a spectrum of academic and non-academic participants, support other kinds of advocacy, including toward disciplinary change and community diversification. These forms of activism and advocacy, while less immediately relevant to broader social causes, may play an important role in the impact of the cultural record emergent from community-based projects, given the increasing convergence of public humanities scholarship and community archiving initiatives. Disciplinary changes, like those advocated within our case studies, can promote the public impact of humanities and cultural work both inside and outside of the academy.

Future work will incorporate analysis of a fourth and final case study, of the Enslaved.org project, which is an explicitly public-facing humanities project. Through further analysis across all cases, we hope to flesh out a fuller set of sustainability factors for community-based digital collections and digital scholarship, beyond the single factor we have explored in this paper, of how digital projects support community wellbeing. In so doing we will connect this work to emergent, broader literature on the relation of cultural heritage to community resilience, with the overarching goal of amplifying the impact of a more equitable, digital cultural record.

ACKNOWLEDGMENTS
We are indebted to our case study partners for their generous collaboration throughout this research, including their review of this paper. We gratefully acknowledge generous support for this work from the Andrew W. Mellon Foundation and the Institute of Museum and Library Services, log number RE-246346-OLS-20.

ABSTRACT
This paper aims to investigate the Trustworthy Repositories Audit & Certification (TRAC) process by examining the communication practices and risk communication dynamics among auditors during the audit. Through an in-depth, qualitative analysis of the audit process and the interactions between auditors, this paper provides valuable insights into the importance of diverse backgrounds, effective communication, and consensus building in the assessment of TRAC checklist requirements. Furthermore, the paper highlights potential areas of improvement within the audit process, addressing concerns related to disagreements, reliance on leadership, and the comprehensiveness of risk identification and communication.

KEYWORDS

INTRODUCTION
Much has been written about the essential role that digital repositories play in the curation and preservation of valuable information (e.g., Boyd, 2021; Kriesberg & Kowall, 2020; Thomer et al., 2022). Repositories carry out the vital work of preserving and providing access to a wide array of information, including research data, government information, and cultural heritage information. Processes have been established to evaluate whether the organizations entrusted with this uniquely valuable information are indeed up to the task (e.g., Consultative Committee for Space Data Systems, 2012a; CoreTrustSeal Standards and Certification Board, 2022; nestor Certification Working Group, 2013).

These processes evaluate whether repositories can be considered trustworthy for long-term preservation through a process of risk assessment that asks auditors to review and evaluate evidence submitted by repository staff members against a set of formal criteria (e.g., Consultative Committee for Space Data Systems, 2012a; CoreTrustSeal Standards and Certification Board, 2022; RLG-NARA Digital Repository Certification Task Force, 2007). When an audit process determines that a repository is indeed trustworthy in this regard, they are deemed a Trustworthy Digital Repository (TDR), and may receive certification confirming this status (e.g., Center for Research Libraries, 2010, 2011, 2012, 2013, 2014, 2015, 2018).

The Trustworthy Repositories Audit & Certification (TRAC) process is one such certification system (Center for Research Libraries, n.d.). In this system, auditors play a key role in interpreting the requirements and evaluating documentation of repository policies and practices against those requirements. Despite the central role that auditors play in this process, scholarship about TRAC and other TDR certification systems has not focused on this group.

In this paper we ask the following research questions about the auditors who were involved in conducting TRAC certification audits for the Center for Research Libraries (CRL):

1. In what ways do members of the audit team communicate during a TRAC audit?
2. How do their communication processes influence their perceptions of risk in the context of a TRAC audit?

Our findings indicate that diverse expertise and open communication using a variety of tools were essential elements of the TRAC certification process. Disagreements among audit team members were resolved through iterative discussions, allowing auditors to reach a consensus and achieve a shared understanding of the risks facing repositories in the context of the audit process. And finally, interviewees were confident in the accuracy of risk information communicated during an audit, but were aware that the process did not surface all of the risks facing the repositories that they reviewed.

LITERATURE REVIEW
Trustworthy Digital Repository Audit and Certification
Repositories can be certified as trustworthy for long-term digital preservation via several different systems, such as CoreTrustSeal, nestor, and TRAC (Center for Research Libraries, n.d.; CoreTrustSeal Standards and Certification Board, 2022; nestor Certification Working Group, 2013). All of these certification systems evaluate repositories against a set of criteria that are informed by the Open Archival Information System (OAIS) Model (Consultative Committee for Space Data Systems, 2012b). In this paper, we focus on the TRAC certification process as administered by CRL (Center for Research Libraries, n.d.).
In 1994, the digital preservation community identified a need for trusted organizations to manage, curate, and preserve digital information, and called for a process to certify those organizations as trustworthy (Garrett & Waters, 1996; RLG-NARA Digital Repository Certification Task Force, 2007). The TRAC certification process was developed as a joint effort between CRL, the Research Libraries Group (RLG), the National Archives and Records Administration (NARA), and the Consultative Committee for Space Data Systems (CCSDS) (Yakel, 2007). The checklist for TRAC was published in 2007 (RLG-NARA Digital Repository Certification Task Force, 2007). The ISO 16363 standard formalizing repository certification criteria was approved in 2012, and the ISO 16919 standard creating a process of accreditation for auditors was approved in 2014 (Consultative Committee for Space Data Systems, 2012a, 2014).

Research about TDRs has been critical of various aspects of the certification process such as the Designated Community (e.g., Bettivia, 2016; Frank & Rothfritz, 2023; Moles, 2022), but overall has emphasized the importance of understanding the value proposition of certification (e.g., Donaldson & Russell, 2021). However, scholarship has not yet established whether TDRs are more effective at long-term preservation than other repositories, meaning that the primary goal of certification – to identify and label repositories as trustworthy for long-term preservation – remains an open question (Bak, 2016; Donaldson, 2020; Maemura et al., 2017). Despite these challenges, several benefits of TDR certification have been identified, including increased stakeholder confidence, transparency in documentation, and improvements in repository processes (Donaldson & Russell, 2023; Lindlar & Schwab, 2018).

Much of the literature about TDR certification has consisted of self-reports from organizations about their experiences with certification, both through formal audit processes and self-audits (e.g., CLOCKSS, 2014; Houghton, 2015; Kirchhoff et al., 2010; Kraher et al., 2017). Literature also describes the work of groups who develop standards for TDR certifications (e.g., Dillo & De Leeuw, 2018; Giaretta et al., 2019; L’Hours et al., 2019). Missing from scholarship about TDR certification, and especially about TRAC certification, is empirical research that focuses on the experiences of the individuals and/or groups who carry out the work of the audit and make decisions about whether to award certification to repositories. Understanding their perspectives and experiences is essential for developing a well-rounded understanding of the audit and certification of TDRs.

**Risk and Communication**

Risk is fundamental to digital preservation (e.g., Barons et al., 2021; Conway, 1996; Vermaaten et al., 2012), and repository certification is largely an exercise in risk assessment (e.g., Frank, 2022). Research about TDR certification has tended to emphasize trust rather than risk (e.g., Bak, 2016; Berman et al., 2008; Donaldson & Conway, 2015; Dryden, 2011; Faundeen, 2017), a focus which emphasizes the goal of certification rather than the process or audit outcomes.

Communication influences the ways in which people construct their understanding of risk (e.g., Lachlan et al., 2009; Nelkin, 1989; Renn, 1991). Scholarship about risk communication has argued that perceptions of risk can be amplified or attenuated depending on factors such as the source, audience, and method of communication (Arvai, 2007; Kasperson & Kasperson, 1996; Lachlan et al., 2009). Communicating risk information requires an understanding of the audience (Konheim, 1988). Risk communication has been examined in the context of many different groups and types of actors, taking into consideration both the source and the recipient of information. For example, the involvement of media, government, political actors, scientists, and/or other types of experts can amplify or attenuate messages about risk (Arvai, 2007; Kasperson & Kasperson, 1996; Lachlan et al., 2009).

Different people, if presented with the same risk information, will not necessarily share the same perception of risk. In addition to the source and the audience, it is also important to consider the mode of delivery any time risk information is communicated (Arvai, 2007). For example, relevance of the information source to the recipient of the communication is an important factor influencing risk perception (Lachlan et al., 2009). The social amplification of risk, a theory about the "social experience of risk, behavioral responses, and secondary consequences relating to economic, legal, social, or institutional changes" argues that risk is a social construct and that hazards can interact with social processes to amplify risk and create secondary effects (Renn, 1991, p. 288).

Research has shown that formal risk assessment processes conducted by groups of experts do not necessarily address the questions or concerns that the general public (i.e., non-experts) have – when it comes to risk information, the two groups are often talking past one another (Konheim, 1988). Indeed, Konheim (1988) argues that people tend to trust, for example, their neighbors, more than experts when it comes to risk assessments. This is
relevant for TDR certification, a process in which the expert/non-expert dynamic emerges between stakeholder groups: standard developers and auditors, who are experts in the certification processes, and repository staff members, who are experts in the policies, procedures, and technologies used by their organizations. The expert/non-expert dynamic also emerges within each of these three groups. Members of the audit team during a TDR audit are selected for their particular knowledge and expertise in order to conduct the most thorough audit possible, but they do not have expertise in all aspects of repository management and thus are both experts and non-experts at the same time during their work as audit team members. Rather than TDR certification only being an example of experts communicating risk information about digital repositories to the public, it is also a process in which the stakeholders are both experts and non-experts and must communicate with one another in order to reach a consensus.

The process of TDR certification is one of risk identification and assessment. The goal of this process is for repository staff members to effectively communicate information to a team of auditors, who in turn evaluate that information and communicate their findings to the repository and the general public. Certification is a social process that has the potential to amplify risk information and create secondary effects in the context of digital preservation. Theories of risk perception that emphasize communication help us to understand that it is not only the identification of risk that influences digital preservation outcomes, but also the ways in which that information is communicated and received, and the actions that people take in response to this information.

In the context of a TRAC audit, an area in which communication about risks is particularly salient is the interactions among auditors who are evaluating repositories for certification. Auditors receive information from repository staff members, discuss and share additional information among themselves, and communicate information out to repositories and to broad audiences who may seek out the results of their audits. Communication about risk information between and among members of these different groups may amplify or attenuate risks depending on the mode of communication, the way in which the risk message is communicated, and the relationship between the source and recipient of the message. This has the potential to influence the outcome of TDR audits, and also repository practices if staff members rely on and trust in the expertise of the auditors (e.g., Bostrom, 1997; Wynne, 1992). Professional discourse around digital preservation and TDRs may also influence perceptions of risk for different types of stakeholders depending on their connections to the digital preservation community, and the ways in which the communication norms of this community either match or diverge from the communication norms of their own professional communities.

RESEARCH METHODS
This qualitative paper is part of a research project which investigates the social construction risk in digital preservation, focusing on the TRAC audit and certification process. The study involved 42 interviews with standard developers (n = 11), auditors (n = 10), and repository staff members (n = 21). In this paper we draw upon the 10 interviews with auditors who administered TRAC audits via CRL.

Data Collection
In-depth, semi-structured interviews were conducted with developers of the ISO 16363 standard, members of the audit team from CRL, and staff members from TRAC certified repositories. At the time of data collection in 2016, there were six TRAC certified repositories, and all audits had been conducted by CRL, as shown below in Table 1 (Center for Research Libraries, 2010, 2011, 2012, 2013, 2014, 2015).

Table 1. TRAC Certified Repositories

Previous research has demonstrated that the work of digital preservation involves collaboration across three main functional areas: digital preservation, IT, and repository administration (Frank & Yakel, 2013). The auditors who
were interviewed held professional roles in digital preservation (n = 4) and repository administration (n = 6). The audit team for TRAC audits consisted of official auditors, as well as an advisory board who reviewed documentation and prepared an assessment. For the purposes of this paper, members of both groups are referred to as auditors and/or audit team members, terms which are meant to encompass the range of individuals who were involved in reviewing and auditing repository documentation during the course of a TRAC audit for the six repositories in Table 1 above.

Interviews asked participants to reflect on their experiences with the TRAC certification process and to identify potential sources of risk for digital repositories. They lasted for one to two hours, depending on the role and experiences of the interviewee. All interviews were recorded and transcribed for analysis.

Data Analysis

Interview transcripts were coded in NVivo using a set of codes that included descriptive, analytic, and thematic codes. The code set addressed several themes, including: potential sources of risk for digital repositories, factors that influence the social construction of risk, the TRAC audit process, attitudes about TDR certification, and communication during the audit process. Coding began with a code set that was developed prior to analysis, and additional codes were added during the analysis process as needed. Transcripts were analyzed by a pair of coders working together to achieve an acceptable interrater reliability score. We achieved a Scott’s pi of 0.719 for the subset of interviews with auditors (Craig, 1981; Scott, 1955). Additional analysis focusing on discussions about interaction among members of the audit team was conducted by a single researcher.

Limitations

In this research we encountered problems with memory and recall (Sudman et al., 1996). Interviewees were asked to recall details about events that took place anywhere from three to eight years in the past. As such, we sent copies of the audit reports ahead of the interviews and suggested that interviewees review their own records, calendars, communications, and documentation before, during, and after each interview. Due to the small population of this community, social desirability and expectancy effects were also likely present, as well as inaccuracy in self-reporting and deference effects (Bernard, 2013).

FINDINGS

Our findings are organized into four sub-sections. First, we examine the audit process, the composition of the audit team, and modes of communication among auditors, including tools and platforms used during the audit process. Second, we examine communication processes during an audit, including communication among audit team members, and between the audit team and the staff members of repositories. Third, we explore how disagreements were managed among the audit team. And fourth, we end with an examination of risk communication among audit team members during a TRAC audit.

Audit Process, Team Composition, and Modes of Communication

Interviewees described an audit process in which repository staff members would prepare and submit documentation to meet the requirements in the TRAC checklist. The audit team would review the documentation, asking for additional information when necessary, which happened frequently:

“Always, 100%. I mean, if you ask how often, it always happens. And it’s a question of how much really. There are some repositories that do, have done a really stellar job. Like the [repository] people at [location]. [Full name of organization] did really a spectacular job of generating documentation and having it really very clearly written and addressing really all of the issues. But even in that case there were instances where we needed more information or explanation or something. So it’s always the case that there will be back and forth and the organization will need to add more documentation or better or new versions of documentation to better explain what is happening” (Auditor 06).

The extended audit team (i.e., audit panel members) would prepare recommendations for the auditors who would then conduct a site visit, investigating repository practices and confirming the accuracy of documentation. After the site visit, the full audit team would reconvene to prepare a final assessment and audit report: “It really depends on what kinds of responses we get from the self-audit and the documentation what we decide to look at at the site visit, but we need to confirm all the things that we had questions about and talk to the right people to help clarify other questions. Then we go back to the panel and talk to them about what we found, and then we come out with the report” (Auditor 03).

Interviewees discussed the importance of having a team of auditors with diverse knowledge and expertise, in order to ensure that all areas of the TRAC checklist could be assessed accurately. Several interviewees described situations in which someone with a particular expertise was able to ask questions, or identify a gap in repository documentation, which resulted in a more responsible audit. “Yes, because everything is not black and white. You
know, there’s some areas where you need to rely upon the group expertise, to do an analysis of a component of the metric. So it may be that someone is more familiar with something than somebody else, and they want to double check on something. Or if we want to double check to make sure that we’ve received all the documentation that one would like to have about a certain thing. So there’s a lot of backing each other up, and making sure that we’re right on target. And I think that makes it a more community-based and responsible effort, ‘cause it isn’t just one person coming in, and making a judgment call, exclusively, on their own” (Auditor 10).

The process described was one which required the contributions of multiple individuals with different types of expertise, communicating with one another around a set of documentation in order to evaluate repositories against a checklist of requirements. Multiple points in the process involved written and verbal communication among audit team members with different types of expertise, and the final result was one in which they needed to reach a consensus in order to determine the final outcome of each audit.

Interviewees described a variety of tools and methods that were used in the context of their work as audit team members to communicate with one another. The auditors used a mix of tools and platforms for communication and collaboration, including Google Docs, Excel, email, and various content management systems (CMS). These tools focused on document-centric collaboration, as the goal of the process for most of the audit team was to analyze repository documentation and write a report summarizing their assessment of that documentation.

While simplicity and accessibility were described as important, interviewees acknowledged challenges in finding a system that would work well for everyone. As a result, various communication methods were used, including both synchronous (e.g., group calls) and asynchronous (e.g., collaborative document editing, email, etc.) methods:

“If memory serves me, there were a lot of email ... They produced documents and the documents, we could comment on them. There was a CMS that CRL provided that we had to access, you logged into a member’s area and you could leave comments and that sort of thing. I kind of forget, a lot of organizations or a lot of, sorry, distributed groups at that time we were still using Microsoft Word and Excel. I say still, because they’re never really good at collaborative editing. You had to pass it around via email attachments or you had to upload it to a CMS. Google Docs became ascendant then. People realized that they could do real, real-time collaboration on documents. I recall lots of emails where we had discussions via email. We had regular, or not regular but a number of meetings, phone calls like teleconferences. And I do recall uploading documents to a CMS after we commented on them” (Auditor 09).

The general theme among interviewees was a pragmatic approach to collaborative tools that facilitated communication between audit team members without boxing them in to any one system or platform.

**Communication Processes**

We found that communication processes among audit team members were open, with regular synchronous and asynchronous interactions. In contrast, communication between auditors and the staff members of repositories under review were highly controlled, with one person managing all communications between the two groups.

**Among Auditors**

When discussing their experiences and interaction with one another, interviewees discussed the importance of communication and interaction to share knowledge across diverse areas of expertise. An open and supportive environment among auditors allowed them to ask questions and engage in collective decision-making. Most said that they were in regular communication through the process, and that this allowed them to divide tasks amongst themselves in order to distribute the workload and allow each auditor to contribute in areas relevant to their own expertise.

For each TRAC audit the team of auditors was broken down into smaller groups, depending on their areas of expertise. Different subgroups chose to communicate in different ways and with varying frequency. For example, Auditor 04 explained a process in which the team was in regular communication via email, with meetings as needed: “I don’t remember but it would seem like it would be monthly or every six weeks. Sometimes it depends on how quickly we get responses back from the repository as questions come up and we put them to the repository. Within the subgroups there is often just a steady low-level email conversation going on.”

In contrast, Auditor 06 described a process of regular conference calls, “during that process we generally break up into smaller groups and focus on a particular section of the three main sections of the audit. And meet via conference call, usually, to discuss issues or questions and then write up a summary report for the auditors and give it to them. And then there are regular calls of the whole group to discuss them.”

Auditor 08 said that the frequency of communication depended on the quality of documentation submitted by each repository, and the amount of additional documentation that auditors would need to request:
One interviewee, however, expressed uncertainty about the communication among the audit team. Auditor 09 explained that the process was opaque, and that he had the impression that decisions were being made behind the scenes which influenced her work but to which she was not privy:

“There were times when I distinctly recall that I thought there was a lot of things had gone on between communication cycles. I didn’t really think too much of it at the time, because I thought, we’re just giving our input. The people at CRL are, they’re actually doing the work of collecting all this information and putting it into their, kind of, their packages and their envelopes and templates. There were honestly, there were times and it may just have been an artifact of me having a busy schedule and not paying attention or something, but there were times when I felt like there was a lot of, there were side discussions going on that had shaped the questions that I was not being asked” (Auditor 09).

Interviewees described adaptable communication processes that varied depending on the conditions of each repository audit and on the preferences of the sub-groups within the audit team. Some interviewees spoke with confidence about these processes, while others found them to be opaque. The lack of standardization was helpful for a process that needed to adapt to the conditions of each individual audit. However, we argue that it also had the potential to be problematic in light of the fact that the certification process was meant to assess repositories based on a clear set of criteria in order to produce results that could be compared across audits.

**Between Auditors and Repository Staff**

A feature of the TRAC audit process is the limited interaction between members of the audit team and staff members from the repositories being audited. “The panel never really talks to the repository” (Auditor 03). Interviewees explained that communication with repository staff was typically channeled through a single point of contact in order to streamline the process and ensure consistency. This separation had the benefit of maintaining a degree of separation between auditors and the staff members of the repositories under review, as it was likely that members of the two groups would know – or at least be familiar with – one another: “No, I think we were over to the side. CRL dealt with them and us, even though these are people that I work with all the time, the staff at [repository], but we didn’t go to them directly, no” (Auditor 07).

Interviewees explained that the initial documentation provided by the repositories was not sufficiently clear or comprehensive enough for their needs, necessitating clarification and/or additional documentation. The additional back-and-forth required to meet this need was channeled through the single point of contact described above. While this simplified the process in some ways, limiting the number of requests that repository staff members would receive, it also created opportunities for miscommunication by having information travel across multiple people, like a game of telephone:

“[T]here's usually some more back and forth because it invariably happens, they'll mention something. I'll remember it, and then I'll be like, "Wait a minute. I need to see that. They talked about it, but I didn't see it," or something along those lines, so I need to do that sort of thing. Then sometimes, we'll go back to the panel, and they'll be like, "Wait a minute. What about this?" We'll have to go back and talk to them about that. Then sometimes if there's deficits or there's something that needs to be fixed, there's a lot of back and forth about that. If we found out that they didn't have some sort of system for checking their files or something along those lines, we'd want to see them doing that before we could certify them, so there would be all of that hand holding, too” (Auditor 03).

Communication between auditors and repository staff members was channeled through one representative from each side of the audit process. This served to streamline communication and shield auditors from potential conflicts of
interest although people with connections to the repositories, and/or staff members of those repositories, were still able to participate in the process. The streamlining did not always save time or make the process more efficient, however, because the specific people handling communication between the audit team and the repository staff did not necessarily have expertise in areas relevant to the discussion.

**Managing Disagreements Among Auditors**

Interviewees described instances of mild disagreement among members of the audit team. When disagreements would arise, they were addressed through iterative rounds of discussion and deliberation. Auditors would work together to resolve disagreements, reaching a shared understanding and consensus in order to ensure that the final result was one that they could all support.

In some cases, disagreements were resolved through discussion and negotiation: “There's certainly disagreement about, as we're discussing, as we move through each of the sections when talking about the individual items and the documentation provided by the organizations there are disagreements. There have been disagreements about, as we talk about any particular item, about the significance of how serious somebody felt a problem might be, or just a range of opinion about how to assess any particular item. But we talk through them and come to an agreement that’s in the process. And I think that by the end of the process everybody agrees with, and is ready to sign off on, the assessment that CRL comes to” (Auditor 06).

In other cases, interviewees deferred to the opinions of CRL leadership in resolving disagreements. Auditor 08 explained that when the audit team had trouble resolving a disagreement, they would rely on the opinion of a particular high-ranking staff member at CRL, “When we had questions, we would defer to [name] at CRL, who was the most experienced person with all of this, with more than [number of years] of doing this kind of thing.” This practice seems to run counter to the design of the audit process, in which people were brought in to the team for their particular expertise in order to inform and advise CRL staff.

Auditors also recognized that there was a balance between seeking more information and the diminishing returns of excess detail. They were able to achieve consensus about how much information was needed to resolve disagreements, in order to assess each repository for TRAC certification. Auditor 08 explained that through the process, auditors came to see that there was a point at which more information did not necessarily help the team make a determination about the repository being evaluated. “You could always ask for more and more information, and at a certain point, the additive piece of what you get out of a certain piece of information becomes less and less” (Auditor 08).

Interviewees characterized disagreements as opportunities for communication amongst audit team members, and to request additional information from repository staff members. Some found that there were limits to how much conflict could be resolved with additional documentation. Others were over-reliant on the opinions of CRL leadership, a group of people who were themselves relying on the audit team members for their expert assessments.

**Communicating Risk**

Interviewees were confident that information about risks was communicated accurately among audit team members. When asked directly, Auditor 07 was unequivocally confident in the accuracy of risk information shared among audit team members. “Yea, I felt confident in that, as well.” However, some were less confident that the process could surface all the relevant risks facing the repositories being audited: “I'm pretty confident about that because of the way those risks are shared, because of the report on the site visits that come up in discussions that follow. There's usually a conference call discussion that's part of the ... there's always a conference call discussion that's part of the process. The folks who are involved in the site visit are giving their perspective and addressing questions which spawn more questions. Through that I think all the risks identified come up. Obviously, have we identified all the risks? Probably not” (Auditor 04).

It was important for members of the audit team to have diverse backgrounds and different types of expertise, in order to inform all of the aspects of the TRAC requirements. Auditor 06 explained that in addition to needing sufficient expertise, it was also important for diverse perspectives in order to prevent over-emphasis on any one aspect of the repository in a process whose goal was a comprehensive analysis of each digital repository:

> “And the importance of having people from organizations on this advisory committee helped shape that more consistently so that there weren’t people with particular hobby horses always insisting on certain ways of doing things. You could have a multiplicity and heterogeneity of backgrounds to temper ... Because the standard doesn’t prescribe any particular, doesn’t prescribe a whole lot really. It really asks, for the most part whether what the repository is doing meets the expectation and understandings of its members. And so that’s what we’re trying to assess is whether they can, first explain what they’re doing, and then second whether this meets what they’ve told their members they’re doing and the members have agreed.”
Besides recognizing the significance of diverse viewpoints for assessing a repository against all TRAC criteria, which evaluate a repository's risk assessment, interviewees were at ease discussing risk-related matters with each other. Auditor 04 expressed confidence about discussing risk, and asking for input from other audit team members, “I felt very free to contact my colleagues and say, ‘I don’t understand this, or this seems like a risk to me. Am I reading this correctly?’ Or to check in on things that I didn’t feel comfortable with before we went to the larger group” (Auditor 04).

In the context of a TRAC audit, a process that evaluates trustworthiness for digital preservation through a process of risk assessment, audit team members were confident that communication about risk information was accurate but were aware that the risk information communicated was not comprehensive. They relied on the varied types of expertise of their audit team members to reach accurate conclusions about the risks facing each repository.

**DISCUSSION**

Auditors play a central role in TDR certification as the people responsible for interpreting the checklist requirements and applying them to information provided by repositories. Despite their position as key players in the audit and certification process, the experiences and attitudes of auditors have been understudied in digital preservation research. This paper extends discussions about TDR certification to include an investigation into the communication practices of auditors across all of the TRAC audits administered by CRL.

While much has been written about the experiences of repositories going through TDR certification processes, and about the development of TDR standards, the experiences of those conducting the audits have received comparatively little attention. Indeed, one of the interviewees in this study identified communication among auditors in TDR certification as an understudied and opaque, part of the audit process:

>“It would be interesting to think about how the communication amongst certification panel members works and what role that plays. I wouldn’t say that it’s a terribly important flaw in the certification process, but let me put it this way, it was probably one of the least well understood aspects of it, from my perspective. One of the more opaque parts of the process. But I’m having difficulty expressing why” (Auditor 09).

Interviewees expressed confidence in the audit process and the resulting certifications. While they did describe challenges in communication during the audit process, their overall attitudes toward the process were positive and indicated that they were able to effectively communicate with one another to reach a consensus. This aligns with previous research about TRAC, which found that auditors as a group shared consistent understandings of the risks facing repositories and the effectiveness of TRAC certification for demonstrating trustworthiness for long-term preservation (Frank, 2022).

We have established that communication influences the ways in which people perceive and construct their understandings of risk (e.g., Arvai, 2007; Cho et al., 2015; Kasperon & Kasperon, 1996; Konheim, 1988). Communication among audit team members during the TRAC audits was pragmatic, allowing sub-groups of auditors to self-organize and use a variety of synchronous and asynchronous modes of communication. Interviewees expressed positive attitudes toward, and deference to the expertise of, CRL leadership and their fellow audit team members. As the organization coordinating the TRAC audits, CRL leadership also selected the members of the audit team for their expert knowledge. This appears to have facilitated a process in which auditors trusted the expertise of their team members in part because they trusted the judgment of those managing the process. This created conditions that allowed them to be confident in the accuracy of risk information that was communicated during the audit process, while also understanding that the risk information was likely not exhaustive.

The relatively smooth communication about risk information among members of the audit team reflected their shared view of the audit team as consisting of people with expertise in digital preservation. It is likely that the selection process, regular communication, and emphasis on the audit team as a group of experts with a shared goal reinforced this perspective while minimizing the differences in their expertise and areas in which audit team members may have lacked a shared understanding of risk. Research seeking to further examine the social amplification of risk in relation to TDR certification should examine perceptions of risk outside of the direct stakeholders in the certification processes (i.e., standard developers, auditors, and repository staff members), in order to investigate secondary effects as described by scholars such as Renn (1991).

Our findings describe a collaborative, multi-disciplinary process for evaluating digital repositories against the TRAC checklist of requirements. The process involved adaptable communication methods and tools, with the audit team tailoring their approach based on specific conditions and preferences. Although the lack of standardization allowed flexibility, it is possible that pragmatic approaches to communication and consensus-building could also lead to concerns about comparability across audits. Communication between auditors and repository staff was channeled through one person, which had the potential to both prevent and create opportunities for miscommunication (e.g.,
Fischhoff et al., 1990). Disagreements were seen as opportunities for further communication, but some interviewees noted that there were limits to the amount of additional information that could be gathered to help resolve those disagreements. We have also identified instances of over-reliance on the opinions of people who were looking to the audit team for expertise and advice. While audit team members were confident in the accuracy of risk information communicated during the TRAC audit process, they were also aware that the information they had could be accurate without being comprehensive.

The high cost of certification, particularly for certification via processes with formal audit teams, brings urgency to the need to understand the inner workings of audit teams in the context of TDR certification processes (e.g., CoreTrustSeal, 2023; PTAB – Primary Trustworthy Digital Repository Authorisation Body Ltd, 2023). Scholarship about risk and audit processes has demonstrated the importance of understanding those who are responsible for interpreting and applying standards to real world organizations (e.g., Vaughan, 1996). The role of auditors in TDR certification is an aspect of certification that has not been the primary focus of empirical research in digital preservation thus far. This paper contributes to the growing body of research about TDR certification by examining communication among auditors during the TRAC certification process.

CONCLUSION
This paper investigates the TRAC audit and certification process, focusing on communication among auditors. The study, based on 10 interviews with audit team members, explores the audit process, communication, disagreements, and risk in TRAC. Findings show that auditors communicated regularly and openly, resolved disagreements through iterative discussions, and recognized the importance of diverse backgrounds for comprehensive analysis. However, they were also aware that the process did not surface all the relevant risks for the repositories being reviewed, and we argue that deference to CRL leadership may have contradicted the TRAC process, in which a team of auditors – selected for their expertise – evaluate a repository in order to determine whether to award certification. Overall, these findings produce a picture of the audit process that inspires confidence in the ability of auditors to work together to evaluate repositories for certification.

Future research should continue to investigate the role that auditors play in TDR certification processes, as this group represents a key component of certification. We also suggest that standards and processes for TDR certification would be strengthened by a stronger focus on the selection of auditors, and by making their work more visible and transparent.

ABSTRACT
Records play an important role in supporting business activities and in ensuring accountability in all types of organisations. However, recordkeeping research has mostly focused on the government sector and on large organisations. Little attention has been paid to small organisations which have limited resources to create and manage the records that they are required to produce and the records that could support their engagement in diversified activities. In this paper, we report the findings from 16 focus group discussions with community-based organisations in Bangladesh which are in the process of transitioning from informal to registered organisations and, in order to do so, must formalise their recordkeeping practices. We discuss the recordkeeping needs and capabilities of these organisations and the recordkeeping problems that they are experiencing. We argue that it is important to support the development of a recordkeeping culture as part of capacity-building in these organisations so that they can function effectively and be sustainable.

INTRODUCTION
Organisational records provide evidence of business activities and support accountability and transparency in organisations of all types and sizes (Cox & Wallace, 2002; Shepherd & Yeo, 2003; Shepherd & McLeod, 2020). By providing an evidence base of resources available and past activities, they also support capacity-building and organisational development. However, different organisations have different information and recordkeeping cultures, different ways of interacting with information and records, which are based on several factors including the national culture and the regional technological infrastructure (Oliver & Foscarini, 2020). For recordkeeping policies and procedures to be effective in ensuring good recordkeeping practices in an organisation, they must be based on the recordkeeping culture(s) of the organisation (Oliver & Foscarini, 2020). Newly-formed organisations which have not had sufficient time to develop a recordkeeping culture, still have to reckon with the cultural preferences of their staff and the local environment in which they are working. In this paper, we argue that in order to support the development of newly-established organisations, it is important to support the development of an awareness of the importance of records as instruments of accountability and capacity-building and the development of a recordkeeping culture based on the cultural preferences of their staff and adapted to the local socio-economic and technical environment.

The recordkeeping literature has focused on large organisations, and particularly on the government sector (e.g. Kennedy & Schauder, 1997; Lowry & Wamukoya, 2014; Duranti & Rogers, 2019). Records management standards (such as ISO 15489) are designed for large organisations with budgets to employ records managers and to finance electronic records management systems. Very little research has been done on the recordkeeping practices of small organisations with limited budgets and little guidance on recordkeeping practices appropriate to their context is available to them. In particular, we could not find any study of recordkeeping practices of informal grassroots organisations in a developing country.

In this paper, we discuss the recordkeeping needs and capabilities of community-based organisations in Bangladesh, which are in the process of transitioning from informal grassroots organisations to registered organisations, and the development of a recordkeeping culture in those organisations. Our research studied 8 grassroots community-based organisations led by middle-aged people and 8 community-based youth organisations led by young people (18-35 years old) in 4 different parts of the country. All of these organisations had been supported by local non-governmental organisations (NGOs) as part of two development projects of an international non-governmental organisation. The 8 grassroots community-based organisations had been included in a resilience-building project which focused on women transformative leadership development through economic empowerment and climate action. The 8 youth organisations had been involved in a youth empowerment project which focused on skill development for exploring economic opportunities, supporting job placement and entrepreneurship development, enabling youth-led social and climate action in the communities, and advocating for youth rights at the national level.

86th Annual Meeting of the Association for Information Science & Technology | Oct. 27 – 31, 2023 | London, United Kingdom. Author(s) retain copyright, but ASIS&T receives an exclusive publication license.
After a brief review of the literature on recordkeeping in organisations and on recordkeeping culture, we explain our methodology which involved conducting focus group discussions with each of the 16 community-based organisations and interviews with key informants in each location and at the national level. We then present our findings on the recordkeeping needs and capabilities of these organisations and the problems they encounter in managing their records. We argue that it is important to support these organisations in developing recordkeeping cultures which value records as essential tools for accountability and for capability development, and which are aligned with the culture of the organisations’ members and the resources available locally so that they can be sustainable.

LITERATURE REVIEW
Records are defined in the international standard ISO 15489:2016 as “information created, received, and maintained as evidence and as an asset by an organization or person, in pursuit of legal obligations or in the transaction of business” (International Organization for Standardization, 2016). Records play an important role in organisations as instruments of accountability (Hurley, 2005). They provide evidence of transactions and help to constitute an evidence base of the activities undertaken by the organisations and the lessons learnt from them. Therefore, the management of the records created in the organisation and the setting up of one (or several) recordkeeping system(s) to manage these records are essential activities that must be performed in every organisation. In this paper, we adopt the records continuum-based definition of recordkeeping as “making and maintaining complete, accurate and reliable evidence of business transactions in the form of recorded evidence” (Standards Australia, 1996).

Recordkeeping includes the design of recordkeeping systems to accommodate records before records are created; the creation of records as evidence of activities of all sorts; and the management of records as evidence of these activities as well as the management of archives of long-term value (McKemmish et al., 2010; McKemmish, 2017). Therefore, our research is interested in records that the organisations in our study must keep as evidence of their activities and the records that they may want to create and preserve to support capacity-building and the development of an organisational memory, as well as in the proactive development of recordkeeping systems to manage those records.

Records management research has mostly focused on large organisations and on the government sector. Most authors have been concerned with assessing whether organisations’ records management practices met legislative and international standards’ guidelines for records management and with determining how their adherence to best practice frameworks could be improved. The literature on records management in developing countries has been mostly concerned with the adoption of digital records management systems to improve records management practices and with efforts to develop digital skills, particularly in the government sector (Lowry and Wamukoya, 2014; Busari, 2019; Mutsagondo, 2023).

A small number of studies have looked at records management practices in small and medium-size enterprises (SMEs) (Okello-Obura, 2012; Ghasia et al., 2017; Ajibade & Khayundi, 2017, 2018). Webster et al.’s (1999) study of 62 SMEs in North-East England discovered a correlation between the existence of a formal management structure in the organisations and the number of records management procedures in place, but the authors did not find a correlation between the size of the enterprises and the quality of their records management practices. Balagoei’s (2019) more recent study of 75 SMEs in Sri Lanka found that records management practices have a “significant positive influence” on the business performance of those enterprises, while a study of top and mid-level managers in small and medium enterprises in Bangladesh conducted by Hosain (2019) showed a correlation between records management performance and organisational performance.

However, the SMEs in those studies are organisations with paid administrative staff and organisational systems. Studies of recordkeeping practices in organisations run by volunteers are rare. Yet, as Joseph (2016, p. 330) wrote, many community groups face “considerable difficulties in capturing, managing and accessing their information assets”. Joseph (2015, 2016) studied recordkeeping practices in two historical motor-sport community organisations in Australia, one being a national confederation with paid staff and the other one an affiliated club run by volunteers. Like in the records management studies previously mentioned, her focus was to assess whether the recordkeeping practices of these organisations conformed to international standards. Although she looked at the management of current records, she was particularly interested in the preservation of records for their cultural value. She observed that in those two organisations, recordkeeping roles were often assumed by unskilled members and that practices often did not conform to best practice standards. A more recent study by Courtney (2022) looked at recordkeeping practices in an amateur choir in London which relied entirely on volunteers to manage its records and archives. She observed that because records were managed by volunteers, they were dispersed between several locations and the systems were informal, and she commented that since the organisation has to rely on volunteers, it is important to take into account the preferences of the members and their information culture.
Whereas most of the recordkeeping literature has been concerned with assessing whether organisations were correctly managing records in accordance with legislation and best practice standards and with finding ways of improving recordkeeping practices in organisations so that they comply with laws and standards, a growing strand of research argues that to be effective and sustainable, recordkeeping practices must be adapted to the information culture of the organisations (Oliver and Foscarini, 2020; Oliver at al., 2018; Lian et al., 2022; Frings-Hessami & Oliver, 2022a, 2022b). Recordkeeping in an organisation is impacted by the information culture of the organisation. Every organisation, whatever its size, has ways of interacting with information, which are influenced by the socio-cultural and technical environment in which it is situated and by the cultural background, knowledge and skills of its employees. Oliver & Foscarini (2014, p. 11) defined information culture as “the values accorded to information, and attitudes towards it, specifically within organizational contexts”. Research has shown the importance of taking into account the context in which recordkeeping activities are performed (Oliver, 2008) and adopting a human-centred approach to the management of information in organisations (Lian et al., 2022). The information culture of an organisation is influenced by many factors, including the national and regional culture, the organisation type, its purpose and its history, its organisational structure, the personality of its leaders and the background and skills of its employees (Oliver, 2008; Choo et al., 2008; Lian et al., 2022). Oliver and Foscarini (2020) developed a 3-level Information Culture Framework to analyse the information culture of organisations, which identifies the factors that are easy to change in order to improve information practices in an organisation, the factors that are harder to change, and the factors that are very difficult to change because they are based on deep-seated cultural preferences or on external elements. The latter, the Level 1 factors, include the preferences for information formats (e.g. oral communication vs. written communication, images vs. texts) and the regional technological infrastructure. Factors at Level 2 that are easier to change include the information-related competencies of the employees, in particular their information and digital literacy skills, which can be improved through training programs. Oliver and Foscarini argued that the factors that are the easiest to change, the Level 3 factors, are the information governance model and the recordkeeping system and tools used in the organisation, which can be changed through policy decisions. However, they asserted that the systems in place in the organisations should take into account the cultural information preferences of the employees to enable those systems to be used efficiently.

In the context of Bangladesh, Frings-Hessami & Oliver’s (2022a) study of information culture in an INGO in Bangladesh showed that it is important for the design of information and recordkeeping systems to take into account the Bangladeshi employees’ preference for oral communication and for the organisation’s formal systems to allow the use of Bangla language to encourage their use.

However, all the studies of information and recordkeeping cultures have been conducted in established organisations. We did not find any previous study of information and recordkeeping culture in newly-formed organisations that have to develop a recordkeeping culture when the organisation is set up and where the members given responsibility for recordkeeping have no previous experience of creating and managing organisational records. Therefore, our research with community-based organisations in Bangladesh is innovative both for its focus on grassroots organisations in a developing country and for its focus on newly-established organisations.

**CONTEXT: COMMUNITY-BASED ORGANISATIONS IN BANGLADESH**

Bangladesh was chosen as the research context because hundreds of NGOs have been facilitating community-based groups and supporting them to become formalised and registered (Cawood, 2021; Datta, 2007; Sultana, Ahmed & Shiratake, 2020). According to Marwell (2004), community-based organisations are organised around a particular geographic place or a “community” with significant regular participation of “community members” in the organisations to operate programs to meet the needs of disadvantaged residents in their local geographic space. These organisations have been contributing to socio-economic and socio-ecological development through community-based management of natural resources, empowering local communities to take community actions on development issues and making the government accountable for the distribution of social benefits and disaster relief. As they mature, these grassroots organisations often opt to transform from informal groups into formal registered organisations like cooperatives (Abegunde, 2009; Emmanucl, 2013; Zook, 2023).

In Bangladesh, based on their mission and goals, scope of activities, internal governance structure, and sources of funding, community-based organisations decide on their suitable organisational forms among several options: non-governmental organisations (NGOs) seeking to receive foreign donations registered under the NGO Affairs Bureau, voluntary social welfare agencies registered under the Department of Social Services or under the Department of Women Affairs (if they are led by women and aimed at supporting women’s well-being), cooperative societies under the Department of Cooperatives, or youth organisations formed by young people for youth development, registered under the Department of Youth Development (ICNL, 2019). While a notable number of community-based organisations opt to become registered as cooperatives and youth organisations, the registration process and associated requirements from different registering government bodies have significant similarities. To be registered as a cooperative society under the Department of Cooperatives, a community-based organisation needs to apply by...
using the prescribed application form, pay a registration fee based on the nature of the cooperative and submit required documents along with the application. Considering the nature of cooperative societies, cooperatives need to demonstrate a minimum paid-up share capital received from shareholders or cooperatives members. After receiving the application, a sub-district Cooperatives officer makes an inspection, checks the submitted documents and writes a findings report to the district office of the Cooperatives Department. If the report is satisfactory, the district Cooperatives office issues the registration certificate. The whole process requires around 2 months. However, if the application is not accepted because of an unsatisfactory report, the community-based organisation can appeal to the Department of Cooperatives within 30 working days and the appeal process is completed within 30 working days. For youth organisations wanting to be registered under the Department of Youth Development, the process and timeline are the same although some requirements related to the amount of the registration fee and demonstrating share capital are different (ICNL, 2019).

Recordkeeping plays a key role in this process because organisations must keep and present some types of records that need to be submitted as supporting documents with the application form for registration. A memorandum of association/constitution with stamp on each page in the prescribed format and signed by the organisation’s president and general secretary is one such record that community-based organisations need to keep and submit during the process. They also need to keep records of the details of their executive committee members, meeting minutes for previous meetings, annual financial report for previous years, updated bank account statement, attested photo and copy of the national identity cards (NID) of the organisation’s president and general secretary, share register, deposit register, loan register, cash book, etc. (ICNL, 2019).

Therefore, records play an important role in the registration and in the development of the community-based organisations and youth groups into formally recognised organisations. Our research project investigated the current recordkeeping practices of community-based organisations in 4 locations in the districts of Satkhira, Nilphamari, Barishal and Rangpur with the aim of identifying challenges and opportunities for recordkeeping in those organisations. These 4 locations are all in climate-vulnerable geographic regions of Bangladesh. In our research, we got access to 16 organisations (4 in each location) that recently progressed from informal community-based groups to become registered organisations

**METHODOLOGY**

Our research used a qualitative case study design with focus groups discussions (FGDs) and semi-structured interviews. We conducted FGDs with 16 organisations in 4 locations in different parts of the country, 4 in each locations. In 2 locations (Shyamnagar in the district of Satkhira and Dimla in Nilphamari district), we worked with grassroots community-based organisations; in the other 2 (Bakergonj in Barishal district and Mithapukur in Rangpur district) with youth organisations. All these organisations had taken part in development projects supported at the national level by an international NGO and at the local level by local NGOs. The grassroots community-based organisations had been included in a large development program which aimed at strengthening community resilience in the most vulnerable agroecological regions of the country by fostering economic empowerment and women’s leadership. Most of these organisations had been founded in 2010 and achieved registration as cooperatives in 2020 or 2021. The youth organisations had been included in a youth development program for young men and women between the ages of 18 and 35 that focused on skills development. They were founded later than the grassroots community-based organisations, in 2017-18, but they achieved registration faster, with most of them being registered in 2019-20.

The FGDs were organised between April and July 2022. Each FGD comprised 6-10 members of one organisation, in most cases including the president, vice-president, general secretary and treasurer. In each location, we also conducted 5 interviews with local-government elected representatives, staff from the local NGOs who were supporting the community-based organisations, and officers from the Department of Youth Development (responsible for the registration of youth organisations) or the Department of Cooperatives (responsible for the registration of the grassroots community-based organisations as cooperatives) as appropriate. In addition, we interviewed one official from the Department of Cooperatives at the national level, and two employees of the international NGO who had worked with the programs that supported the community-based organisations. In total, 23 interviews were conducted. FGD and interview questions were prepared by the Australian-based authors. FGD participants were asked questions about the types of records their organisation created, the ways those records were managed, the problems they encountered with managing records, the support they received from the local NGOs and government departments in matter of recordkeeping, and their future plans for improving recordkeeping in their organisation. The key informants answered questions about the records that need to be presented at the time of registration, about their understanding of the recordkeeping capabilities of the community-based organisations, and about whether they supported the organisations to improve their recordkeeping practices. The FGDs and interviews were conducted face-to-face by a Bangladeshi team consisting of two research collaborators and seven students/research assistants, in accordance with the ethics approval from the Australian university. The interviews of
the 3 informants at the national level were conducted remotely by one of the authors through video conference. All the FGDs and interviews were done in Bangla, translated into English, then coded and analysed thematically by the authors.

FINDINGS
Records kept by the community-based organisations
The findings from our research show many limitations in the recordkeeping practices of the community-based organisations due to a lack of resources and skills to manage records. Their recordkeeping systems are mostly paper-based and ad-hoc and they do not have a formal strategy for creating, capturing and preserving records. As the community-based organisations were formed during projects supported by NGOs, they received a lot of assistance from the NGOs with the activities they performed, including with keeping records of these activities. Their transition towards registered organisations near the end of the funded projects was also supported by the NGOs. From that time onwards, they had to start creating and keeping more records because they were required to present a number of records when applying for registration and to keep those records since they could be audited. For grassroots organisations, records required for registration as cooperatives included a list of members, a resolution book, copies of the identity cards of committee members, photos of leaders, and bank account papers showing a positive balance. After registration, they must keep those records and keep a resolution book, meeting minutes, attendance sheets with signatures, and evidence of all financial transactions. Youth organisations who wanted to register with the Department of Youth Development also needed a constitution and a membership policy. After registration, they must keep all the records they presented for registration, hold frequent meetings and keep evidence of the events they organise and of all their financial transactions. The registration process was supported by the local cooperatives and youth development officials and by the local NGOs which advised them on the records that they needed to create and keep, their format and their content. After registration, the cooperatives can provide micro loans to their members and the youth organisations can apply for funding to organise events, all of which require the creation and management of more records and better recordkeeping practices.

The organisations generally keep paper records in a trunk in the house of one (or several) of their members because most of the organisations do not have office space. The records move to another house when responsibilities change in the organisation. This places the records at a risk of being destroyed by cyclones and floods, poses security and privacy risks, and makes it difficult for other members to access them. In case of leadership change, there are risks of records being lost. The participants were aware of these risks, but most of the grassroots organisations could not afford to have an office with lockable cabinets to store their records more safely.

Digital capabilities
Capacities to create digital records or to digitise records were very limited particularly in the grassroots organisations. Only one of those organisations had a laptop which its members could use to keep organisational records. The digital literacy skills of the members and their awareness of privacy and cybersecurity issues were very limited. Not all of them owned smartphones and their access to the internet was limited. However, some members who owned smartphones sometimes took photos of important documents to keep them as a backup on their phones in case the paper records would get damaged. One FGD participant explained that:

Many times, the children went to play and ruined the passbook given by the organisation, or the notebook got burned or got wet in the water. Therefore, as a precautionary measure, we keep a personal record to keep track of our transactions with the organisation (vice-president, grassroot community-based organisation (CBO) 2, Shyamnagar).

This precaution was taken at the individual level, but two of the grassroots organisations from Shyamnagar were interested in managing their organisational records digitally and in hiring a person with digital skills to help them with this.

The youth organisations’ digital capabilities were higher, but varied among the groups. Seven out of the 8 youth organisations kept some digital records, but these were scanned copies kept as a backup rather than records created in a digital system. Three of the organisations had laptops on which they kept scanned copies of important records. Two of them also kept copies on memory sticks as an additional backup, while the third one uploaded copies in Google Drive. The youth organisations which did not have an organisational laptop nevertheless kept digital copies of some important records. In two of the organisations, members kept them as photos on their phones, while one organisation kept them in Google Drive and the member of another one went to a computer shop to scan their important records and save them on a memory stick, and also uploaded them on Google Drive. In addition, all the youth organisations except one had a Facebook page which they used to advertise their events and share information and on which they kept photos of their activities. This is an important difference with the grassroots organisations which did collectively use Facebook although some members might have personal accounts.
Impact of registration on recordkeeping

Noticeable improvements in recordkeeping practices can be linked with the registration process. Because of the registration requirements, the organisations keep more records and their records are better organised, but the grassroots organisations find it stressful and time-consuming to keep all the records that they are required to keep, especially the financial records associated with making small loans to members. Currently, the people responsible for looking after their records are not paid despite the considerable amount of time that they must spend on recordkeeping. Many participants agreed that the members in charge of the records needed more training and should be paid for their work. Several of them said that, when their finances would allow it, their organisation would pay those people or hire someone with recordkeeping expertise. Participants from Shyamnagar were particularly interested in getting training on digital recordkeeping processes as they believed that digital recordkeeping would make their work easier.

However, most of the organisations did not have a recordkeeping strategy since their recordkeeping had developed to meet external requirements rather than as the result of a need to build a memory base. Both in the grassroots organisations and in the youth organisations, the members’ understanding of the importance of recordkeeping was limited to the records that they were required to keep for accountability purposes. None of the organisations had a recordkeeping policy or even any plan on how long they would keep the records that they had. None of the grassroots organisations showed an interest in building an archive of their activities that they could use to develop the capacities of their members or to document their history.

Reasons to keep records

All the participants from grassroots organisations said that they kept records to follow rules and regulations and for “transparency”. Since they started giving small loans, there were more transactions to keep track of and it was important to write them down to remember them. Their use of the word “transparency” usually referred to internal transparency (to their members), rather than external transparency (to auditing agencies). Since they were administering small loans, they found it important to keep track of lending transactions as evidence in case any member asked questions about how they had spent the organisation’s money. As one of the participants said, “by keeping all these records, there is transparency among all the committee members; we can trust each other; there is no conflict” (FGD participant, CBO 2, Dimla).

The youth organisations also kept records to follow rules and regulations. They were particularly concerned with the need to keep the records that they needed to present if they wanted to apply for funding. Because they did not administer loans, accountability to their members was less prominent in their answers. Participants from two youth organisations from Bakerganj spoke of the importance of keeping records to support their organisation’s development. When asked what were the benefits of recordkeeping, one FGD participant declared that:

We can find and use these records even after 10 to 15 years. We can look into these records and realise what we have done thus far. Even other organisations can get assistance from us for forming their own organisations. The new members can use the records properly if we store them. It is better if they find them updated and stored correctly (FGD participant, youth organisation (YO) 2, Bakerganj).

Therefore, if they kept their records well, they could use them for their own organisation, but also to assist other groups seeking registration.

Role of the NGOs

The NGOs played a key role in supporting the organisations’ development during the projects they were involved in, including in matters of records and recordkeeping. They assisted them when they were putting together the records required for registration. Officers from the Department of Cooperatives and the Department of Youth Development provided advice about the regulations and the records that the organisations needed to produce when applying for registration. However, their budget was insufficient to provide training for all the new cooperatives. A Department of Cooperatives official from Dimla asserted that training in account keeping was not provided in the sub-district and that the training budget only allowed for 20 people to be trained for the whole division of Rangpur which encompasses 15 million people. The NGOs played a bigger role in assisting the grassroots organisations with obtaining registration, including in the matters of records and recordkeeping, than they did with the youth organisations. According to one NGO officer, during the development project that they supported, the field facilitators checked the records maintained by the community-based organisations: “Whether the records are properly kept in their books, whether or not an unintentional mistake is being made, they are immediately corrected by our field facilitators” (NGO interviewee, Shyamnagar). The project officers and finance officers of the NGO also inspected the grassroots organisations’ records, as the same NGO officer explained: “every 2 months, we [brought] all their transaction documents to our office. Then, I re-check[ed] everything carefully with the help of a finance officer”. An NGO officer from Dimla also reported that they regularly checked the records of the grassroots organisations and helped their members to correct them if they found any mistakes. Both officers said that they
provided training about recordkeeping to the grassroots organisations in their locations. One participant said that the local NGO had helped them in many ways, providing advice on how to keep notes and write resolutions, and telling them what financial records they should keep (CBO 3, Dimla).

The youth organisations also received support from the local NGOs during the project in which they participated. An NGO officer from Mithapukur asserted that they had helped the youth organisations to set up their recordkeeping systems and that at the end of the project, they provided them with a procedure on how to maintain their records. Like the Department of Cooperatives, the Department of Youth Affairs did not provide recordkeeping training to the organisations which were seeking registration, but only informed them on what was required for registration.

According to an NGO officer from Mithapukur:

The government is more focused on skills training. They don’t consider [recordkeeping] as a skill. They consider it as one kind of knowledge. Therefore, the Department of Youth Development, the Department of Social Services or the Department of Cooperatives don’t spend any money on recordkeeping systems or provide any training. They only provide training on poultry farming, domestic animal farming, cow fattening, or goat farming.

His NGO provided some training on writing a constitution and project proposals and on managing accounts, but one of his colleagues asserted that the 3-day training that they had provided was not sufficient and that organisation members were not practicing what they had learnt and still struggled with basic account keeping tasks. He asserted that: “Even though we have given them [the procedure], they don’t maintain [the recordkeeping system] … after handover, if you don’t teach them practically, [the system] … will not be used”. He thought that frequent reminders were needed and that new executive members should be trained, as well as alternates in case some members left the organisations.

DISCUSSION: DEVELOPING A RECORDKEEPING CULTURE

The community-based organisations in our study have taken a short-term view of recordkeeping requirements and do not have a recordkeeping strategy. They have been creating and keeping the records that they needed in order to acquire and maintain registration and for supporting their microcredit activities (grassroots organisations) or for applying for funding (youth organisations). With 1 or 2 exceptions, the organisations do not have a long-term view and do not think of records as tools to support their capacity development. They do not think of the records that they may need later. None of the grassroots organisations has thought of developing an archive documenting their activities, and the youth organisations rely on Facebook to keep photos of events that they have organised.

There have been noticeable improvements in their recordkeeping practices since the organisations became registered. However, because the registration process was driven and supported by NGOs and because this only took place at the end of the funded development projects, the organisations did not have much time to practice and develop their recordkeeping skills and it is doubtful whether they will be able to continue to manage their records without the support of the NGOs. As the national official from the Department of Cooperatives whom we interviewed commented, these processes could have been more effective if they had happened earlier in the projects and not when the projects were winding down. The organisations currently depend on key leaders to look after their administration and their recordkeeping, rather than on trained staff employed to do it. This poses a risk for the organisations since if these leaders leave the organisations, there may not be someone with the necessary skills to replace them. This is particularly the case for the youth organisations because the youths may leave when they get a job. This is less likely to happen in the grassroots organisations, which are more stable, but the skills level of their members is lower and recordkeeping tasks are a heavier burden for them, which could make it difficult to find members who agree to do them.

The environment in which the community-based organisations operate and the resources available to them make it difficult to improve their recordkeeping practices. They are relying on volunteers to manage their records, they do not have a budget to employ staff with recordkeeping expertise or even to buy a computer, and their members’ digital skills are low. Moreover, in rural areas, internet connectivity is poor and power cuts are frequent. Although many participants believe that a transition to digital recordkeeping would reduce the risk of records being lost during cyclones and floods, the use of digital records in that environment could lead to critical records being lost due to a shortage of skilled people to maintain the recordkeeping systems or a lack of resources to continue using those systems. When making recommendations regarding recordkeeping systems for these organisations, it is essential to take into account the local technological infrastructure, the capabilities of their members and their cultural preferences for some types of records. Frings-Hessami and Oliver (2022a) observed that Bangladeshi employees in the Dhaka branch of an INGO preferred to ask colleagues for information rather than consult records of past activities in information systems. The cultural preference in Bangladesh for oral communication over written communication is a factor that is not favourable to the creation, management and use of records in organisations.
Nevertheless, for the organisations to maintain their registration and to develop their capacities, it is essential that they develop a recordkeeping culture that values records as tools of accountability and capacity-building. In order to do this, they need a leadership group who will encourage that process and training for key leaders to develop their recordkeeping skills. Webster et al. (1999) have observed that having a formal management structure was a factor that was linked with better recordkeeping practices, whatever the size of the organisations. In the case of the community-based organisations in our study, key leaders who understand the importance of recordkeeping and have a vision for building capacities in their organisations could make a significant difference.

Some of the problems faced by these organisations are common in community-based organisations run by volunteers. Although the Australian context in which the community organisations studied by Joseph (2015) operated is very different from that of the organisations in our research, most of the challenges listed by Joseph – difficulty in sourcing, organising and managing records and archives; challenges in accessing past information; inconsistent information management practices; lack of guidelines or principles to follow; assumption of roles by unskilled members; lack of awareness about information management professional standards; and absence of a national service to assist in guiding good practice – apply to the Bangladeshi community-based organisations, and at a higher degree than they apply to Australian organisations. As observed by Courtney (2022), because community organisations have to rely on volunteers to manage their records, it is particularly important for them to take the preferences of the volunteers and the culture of the organisations into account. If people are expected to accomplish some tasks for an organisation in their own time, it is crucial that they understand the importance of what they are doing and that they are given some freedom in the way they do it.

For a recordkeeping program to be successful, it needs to take into account the information culture of the organisation. Training programs to develop the digital literacy skills of the people in charge of recordkeeping must be based on the Level 1 factors from Oliver and Foscarini’s Information Culture Framework, that is their preference for some types of information formats and the regional technological infrastructure (Oliver & Foscarini, 2020). In the case of the Bangladeshi organisations in our study, the regional technological infrastructure is a particularly important factor, which restricts and poses risks for the use of digital records. Whereas the digital capacity of the people can be increased through training, the local technological infrastructure will be more difficult to change. The Bangladeshi government is pushing for the use of digital services throughout the country (Government of Bangladesh, 2019), but in some of the areas where we conducted our research, the technological infrastructure is not ready to support this and not all the members of the grassroots organisations have access to smartphones, which would restrict their access to their organisation’s records if records were to be kept only in digital format. At present, some of the organisations (both grassroots organisations and youth organisations) are keeping digital records as backups for their paper records. This is a prudent risk management strategy that had previously been observed in one of the locations from our study (Frings-Hessami, 2023). In the present circumstances, it would not be prudent to move entirely to a digital recordkeeping strategy and to discard paper records.

In the next stage of our research, we are planning to develop an action research project with some of the grassroots organisations and youth organisations to co-design recordkeeping systems that meet their needs in collaboration with a development agency and local NGOs. The preferences of the organisations’ members for some information formats and the technological infrastructure in the areas will be key factors to be taken into consideration. Since the cultural preferences are likely to be similar in other community-based organisations in the same areas, we envisage that this project may lead to the development of a series of recordkeeping processes that may be used for other community-based organisations in Bangladesh and recommendations for NGOs and government departments which work with those organisations on practical actions to support recordkeeping practices in those organisations.

**CONCLUSION**

The recordkeeping literature has not paid much attention to the management of records in community organisations. Our research into the recordkeeping practices of community-based organisations in rural areas of Bangladesh which are in the process of transitioning from informal to registered organisations is innovative for two reasons, firstly for its focus on community-based organisations in a developing country, and secondly for its concern with the development of a recordkeeping culture and recordkeeping practices in new organisations. The findings from FGDs with 16 community-based organisations in 4 different districts discussed in this paper showed that these organisations have limited capacities to manage the records that they are required to keep to maintain their registration and to support their activities, and that they have not yet developed a recordkeeping culture that values records as instruments of accountability and capacity-building. We have argued that in order to encourage better recordkeeping practices in those organisations, it is important to foster the development of recordkeeping cultures based on the information preferences of their members and adapted to the local technological environments.

ABSTRACT
Twitter has emerged as an important forum for discussion among academic librarians. In this research, we take a mixed-methods approach to study the thematic content and sentiment of tweets authored by academic librarians in the United States, Canada, and the United Kingdom. We found differences in the semantic content and themes present in the data from each country that point to differences in how librarians in each country engage on Twitter. While more work remains to be done, we cast new light on how members of professional communities use social media. Our qualitative analysis identified 11 thematic categories in academic librarians’ Twitter discussions, focusing on professional topics. UK librarians exhibited a higher frequency of labor- and employment-related terms compared to their US and Canadian counterparts. Sentiment ratios for US and Canadian tweets were similar, while the UK displayed nearly double the positive-to-negative tweet ratio. We also present a methodological intervention comparing two different sentiment analysis methods, VADER, and Zero-Shot Learning (ZSL), to classify posts by academic librarians. ZSL significantly outperformed the off-the-shelf classifier, highlighting how accurate prediction is possible without annotated training data.

KEYWORDS
Social Media, Academic Librarians, Thematic Analysis, Sentiment Analysis, Zero-Shot Learning

INTRODUCTION
Over the past decade and a half, the social media platform Twitter has emerged as a prime gathering place for various professional communities, including those in medicine, public health, academia, law, and journalism. While few professional communities have been as profoundly impacted as journalism, the imprint of Twitter is significant in the realm of librarianship, with numerous librarians participating in discussions and identifying themselves as professionals in the field. Custom hashtags (words or phrases prefaced with a “#”) are now common at library conferences, where organizers use them to prompt online discussions and facilitate exchanging ideas and experiences. For librarians, work, labor, and employment issues have been particularly salient in recent years. The COVID-19 pandemic strained the resources of libraries around the world, and, as perceived cost centers, libraries have often been targeted for budget cuts by governments and educational institutions. Moreover, the perception of librarianship as a “pink collar” profession, coupled with the disproportionate representation of women in the library workforce, has fostered an impression that librarians are poorly compensated and lack prestige compared to professionals with similar levels of education (Rosa & Henke, 2017). However, research on job satisfaction among librarians does not indicate that librarians are less satisfied than other workers. This paper advances our understanding of librarians’ behavior on Twitter and examines the question of job satisfaction through an analysis of librarians’ tweets. More specifically, to what extent do academic librarians tweet about work and employment topics, and are those tweets more negative in sentiment than academic librarians’ tweets overall?

Aggregating tweets by hashtag is a common method of Twitter data collection and has even been applied among the librarian community (Hicks, 2021). However, this paper goes beyond hashtags and seeks to explore the richer data available in the content of tweets shared by librarians and other professionals. Therefore, we approach this work with three research questions.

- **RQ1:** What do academic librarians discuss on Twitter? In particular, what do they write about issues relating to work, labor, and employment?

- **RQ2:** How does the content of academic librarians’ Twitter engagement differ between the United States, Canada, and the United Kingdom?

- **RQ3:** With minimal or no training data, how can we apply and evaluate unsupervised computational methods to analyze the sentiment polarity of academic librarians’ tweets?

By examining these questions, we gain insight into the conversations academic librarians engage in on social media, especially about their professional lives and the sentiment within these discussions. We also explore the potential of unsupervised computational methods to accurately detect the sentiment polarity (positive or negative), with minimal or no training data. To answer the first and second questions, we develop criteria for classifying tweets as about work, labor, and employment using computational methods. We then augment the results by manually annotating the themes in a subset of the tweets. To answer the third question, we use two different approaches for sentiment
analysis, VADER and Zero-Shot Learning (ZSL), and add sentiment labels to our dataset. While VADER is an off-the-shelf classifier that is accessible and easy to implement, ZSL is one of the state-of-the-art approaches popularized by recent developments in generative artificial intelligence (Yadav & Chakraborty, 2021; Wang et al., 2019; Xian et al., 2017). Since our dataset does not contain gold-standard labels, we design a unique evaluation scheme to test and validate the performance of the models.

The rest of the paper is organized as follows. The following section presents relevant literature related to our research, followed by our data collection and preparation process. In the next section, we highlight our methodological approach. Next, we present our results and discuss them. The last two sections conclude the paper and discuss limitations and directions for the future.

RELATED WORKS
In this section, we discuss some of the works related to workplace and academic librarians, social media and professional communities, and the applications of NLP techniques (and sentiment analysis) to Twitter data.

Work and the Academic Library Profession
Job satisfaction, morale, and burnout among librarians and library workers have become favored topics among library and information science researchers (Colon-Aguirre & Webb, 2020; Falcone & McCartin, 2022; Kendrick, 2017; Kendrick & Damasco, 2019; Martin, 2020). The recent surge in such studies reflects broader societal concerns about social justice and institutional accountability, especially in the US academy (Lopez, 2021; Rothman & Barraza Mendoza, 2021; Wilder, 2013). Work in this domain can be divided into several categories: research on job satisfaction, morale, and burnout and, more recently, research on vocational awe.

Research in the first category is largely pragmatic and is concerned with maintaining the librarians’ and staff’s productivity and minimizing turnover. On the other hand, concepts from critical theory have been used to explore how libraries function as centers of power and privilege at the expense of marginalized employees and patrons (Alabi, 2015; Fiedler & Sterling, 2021). It has also highlighted the subjective experience of burnout, fatigue, and emotional labor endured by librarians from diverse identity categories. While research on morale and burnout reveals no evidence that academic librarians experience these issues more than the general population, it acknowledges the existence of abusive practices in academic libraries. In contrast, studies on vocational awe have emphasized the negative aspects of library employment and portray the library profession as exploitative and oppressive toward its members. Recent literature on academic librarians’ job satisfaction and morale has delved into the phenomenology of workplace morale, examining the experience of low morale among librarians (Kendrick, 2017) and the extent to which marginalized groups experience it (Kendrick & Damasco, 2019). Furthermore, research has investigated the extent of “burnout” – the end state of low morale – among academic librarians (Colon-Aguirre & Webb, 2020). Research suggests that although low morale and burnout are real phenomena, they are not experienced at particularly high rates by academic librarians. Researchers have identified triggering events and behaviors, such as workplace abuse by managers and administrators, as potential causes for low morale and burnout among librarians. Relatively little data has been collected in this area thus far, with the largest and only quantitative study by Colon-Aguirre and Webb (2020) garnering 525 full responses.

The term “vocational awe” (Ettrah, 2018) is defined as “the set of ideas, values, and assumptions librarians have about themselves and the profession that results in beliefs that libraries as institutions are inherently good and sacred, and therefore beyond critique” (Ettrah, 2018). However, Ettrah argues that libraries, like other institutions, are shaped by social forces and resist change. In the United States, this implies that libraries have been shaped and influenced by the country’s racist and exclusionary past and, like other institutions, continue to bear its imprint. Subsequent research has extended the theoretical thread, exploring vocational awe in specific subfields of librarianship (Vickers & Yang, 2022) and incorporating vocational awe into new visions of what the expressed professional values of librarians should be (Cheshire & Stout, 2020).

Social Media and Professional Communities
Scholarship on social media and professional communities has explored how platforms such as Twitter have been used for professional development (Singh, 2020), the expression and reconstitution of professional norms and identities (Olausson, 2017), targeted activism (Hicks, 2021), and networking (Mulatiningsih et al., 2013). Methodologically, these studies have utilized interviews, hashtag analysis, and quantitative textual analysis methods, such as sentiment analysis.

In the context of the Library and Information Science (LIS) profession, there has been limited research on social media usage and behavior. An early study of librarians’ Twitter usage employed semi-structured interviews with librarians to understand their motivations for using the platform (Mulatiningsih et al., 2013). The study revealed that most participants used Twitter to support “lifelong learning” and to connect with other librarians. However, the study’s age and small sample (participants) size warrant a fresh inquiry into librarian Twitter usage. Recently, Ming
et al. (2022) assessed library-related discussions on the Reddit platform. Unlike the earlier work, which made only limited use of data drawn from social media platforms, Ming and coauthors gathered a large number of posts made to topical subreddits and used manual coding and computer processing to determine the types of LIS organizations mentioned in the posts, topics of discussion, and factors driving user engagement. They found that the most discussed topics were “library services and usage,” followed by “librarians and jobs.”

**Application of NLP Techniques to Microblogging Data**

Natural Language Processing (NLP) has flourished as the cost of computing power has declined, and new, more user-friendly tools have opened it up to researchers across various disciplines. Traditional NLP methods, including those found in popular libraries such as Python’s NLTK, are oriented toward massive bodies of text rather than the short texts on microblogging platforms like Twitter. Nevertheless, the richness of Twitter as a data source prompted many researchers to adapt ways of working with smaller chunks of information. In particular, researchers have focused on word frequency and sentiment analysis, applying it to problems such as stock price prediction (Rao & Srivastava, 2012), measuring the relative “happiness” of tweets posted in different environments (Loureiro et al., 2022; Schwartz et al., 2019), as well as gauging attitudes towards major world issues and events (Qiao & Jiang, 2021; Rajput et al., 2020).

While frequency analysis involves counting the occurrences of information units, such as words or phrases, within a corpus and computing descriptive statistics to quantify their prevalence, sentiment analysis aims to approximate human judgments about the meaning and semantics of words and phrases. Together, they can help understand the topical content of texts and the cognitive state of the people who generated them. Rao and Srivastava (2012) paired frequency and sentiment analysis of tweets mentioning a selection of major technology companies with stock price information, developing a model (Naive Bayes classifier) capable of predicting price movements based on sentiment. Subsequent research used sentiment analysis methods that did not require large training datasets, but lexicons assessed by human raters. All of these methods assume that the sentiment of a text can be determined by taking the sum of the sentiment values of its component words. One such method, VADER (Valence Aware Dictionary for sEntiment Reasoning), is a rule-based heuristic that classifies input texts as positive, negative, or neutral in sentiment (Hutto & Gilbert, 2014). VADER also considers contextual influences on sentiment, such as emphasis indicators or negation (e.g., “This book is NOT good!”).

Other methods, such as the “hedonometer” approach, are less context-aware but incorporate greater nuance in sentiment values assigned to text features (Dodds & Danforth, 2010). While VADER and older sentiment lexicons like LIWC (Linguistic Inquiry and Word Count) produce binary (positive or negative) or ternary (positive, negative, or neutral) sentiment judgments, the hedonometer approach employs human raters to place words on a scale from most negative to most positive, creating a lexicon for more precise sentiment assessments. Researchers using the hedonometer lexicon have used not only the textual content of tweets but also the geographic data provided by the Twitter API to construct the gradients of sentiment around public parks in San Francisco (Schwartz et al., 2019) and wildfires in Iberia (Loureiro et al., 2022). Natural language processing and machine learning techniques enable researchers to parse large quantities of microblog posts computationally.

**DATA COLLECTION AND PREPARATION**

The data preparation steps are highlighted in Figure 1.

**Data Collection from Twitter**

To address the data collection requirements of this project, we developed (1) a collection of Twitter content authored by librarians, (2) criteria for tagging content as being “about” work, labor, or employment, and (3) a method for determining the relative prevalence of these topics within the content. The population of interest was further narrowed to academic librarians because the modifying term “academic” provide a convenient heuristic to identify population members and the expectation that librarians from a particular subfield within the profession would have more in common than librarians. Data collection for this project commenced with a Twitter search for academic librarians, defining an “academic librarian” as a Twitter user self-identifying as such in their bio. We recorded the screen names and handles of the top 100 public accounts matching this criterion in our search results. Our analysis was restricted to tweets from English-language accounts. Subsequently, we extracted data from these 100 accounts using the Snscrape tool (a social networking service scraper in Python) and associated Python wrapper. We selected the 100 most recent tweets from each account, which could have potentially yielded a maximum of 10,000 tweets (100 * 100 = 10,000). Since not all accounts were prolific posters, the dataset contained fewer than 10,000 tweets (specifically, 9,821). The tweets were collected on September 15, 2022 (several weeks before Elon Musk acquired the platform), and approximately 72% of tweets in the dataset were posted in the year prior to data collection (with ~90% posted in 2020-2022).
Data Cleaning and Processing
After extracting the data, the cleaning process involved removing mentions, hashtags, and URLs, which were subsequently added as features. Each tweet was then converted to lowercase and stripped of punctuation. Country-level geographic information about each Twitter account in the dataset was manually gathered from account details and, when possible, cross-verified using LinkedIn profiles and institutional websites. Most accounts were from the United States, Canada, or the United Kingdom; accounts from these three countries generated 9074 of the 9821 total tweets collected. The residual 747 tweets were not analyzed because we could not identify which country they came from. The data was augmented with a “Country” feature to facilitate country-level analysis.

A critical aspect of data preparation was determining the criteria for classifying a tweet as being “about” work. While various approaches could be employed, this study relied on a “positivistic” or “bibliometric” strategy (Hjoland, 2001), which assesses whether a text is “about” a particular topic based on the words the text contains. While this study did not adopt a formal definition of “work,” we used the common use understanding that work encompassed any activities carried out in exchange for payment, along with related side activities and concepts. Thus, our criterion for determining whether a given tweet was about work was whether the tweet contained one or more work-related keywords. We searched for the word “work” itself, a rough synonym such as “job,” and references to payments such as “pay” and “salary.” Concepts such as “contracts” and “unions,” which relate to work agreements and employment conditions, were all comprehended by our understanding of work. To generate a comprehensive list of work-related keywords, we started with an initial set of work-related terms (“work,” “labor,” “job,” “pay,” “union,” “contract,” “salary,” and “hire”). Using these terms, we expanded the list to create an augmented list of keywords. We leveraged vector representations of our initial keywords to identify the 100 most similar words in the built-in vocabulary of the SpaCy Python library. From this expanded list, we selected only those words that appeared within the corpus of tweets to create the final augmented keyword list. Finally, the dataset was partitioned into three parts, representing accounts from the United States, Canada, and the United Kingdom. This division facilitated country-specific analysis and comparison.

METHODOLOGY
This study analyzed a set of Twitter content created by academic librarians by starting with a set of topic-related terms, augmenting those terms with more terms based on vector similarity, and determining the topic’s prevalence using term frequency. This method allowed us to treat all tweets in our corpus as bearing information. For our analysis, we adopted a mixed methods approach, summarized in Figure 2. We used quantitative methods like word frequency analysis to explore the distribution of the most frequent words in the corpus and for each of the three countries (US, Canada, and UK). Next, we classified the thematic content of a subset of the collected tweets. Using machine learning, we determined the sentiments of the tweets in an unsupervised way and developed evaluation strategies to compare the performance of the prediction. We then dived deeper into the data qualitatively to (1) assess the difference in sentiment in the US, Canada, and the UK; (2) evaluate the prediction performance of the two different computational methods (VADER and ZSL).

Word Frequency Analysis
Our objective was to determine the relative frequency of individual work-related terms in comparison to one another and to all words within the corpus. A word cloud — a graphic that displays a collection of words, with the size of each word proportional to its frequency within a given text — effectively conveys the prominence of work-related terms in the analyzed corpus and highlights the relative frequencies of words. However, considering the data was collected using an augmented list of keywords, we performed three separate analyses — one for all the words in the corpus, one for keywords alone, and the other for text without keywords. By removing the keywords for the
analysis, we gather insights about the most frequent co-occurring words for academic librarians’ work-related tweets.

**Figure 2. Mixed Methods Data Analysis**

**Thematic Analysis**

Thematic analysis is a well-established qualitative method for approaching textual data. Conventional thematic analysis, which we applied to academic librarian tweets, involves a human reviewer identifying themes and ideas present in texts and then creating codes that encompass or generalize those themes, allowing the researcher to identify patterns within the texts (Guest et al., 2012). Thematic analysis originated as a method for studying longer texts generated by in-depth interviews in the context of psychological research (Braun & Clarke, 2006). More recently, it has been adopted in anthropological research (Wutich et al., 2021) and has flourished as a tool for understanding social media data. Such examples include analyzing public reactions (Schneider & Trottier, 2013) and online activism on social media platforms (Xiong et al., 2019). More recent research (Lindstadt et al., 2022; Mohammadi et al., 2022; Nutley et al., 2021; Tahamtan et al., 2021) have also focused on social problems or newsworthy events, including the Covid-19 pandemic. Such events help define research outlines and impose temporal boundaries on them.

We conducted a thematic analysis of a selection of tweets – using NVivo qualitative analysis package – to identify the major themes in our tweet collection. Ideally, these themes should illuminate some of the work- and employment-related topics academic librarians discuss on Twitter. We also wanted to gain insights into the topics being discussed in association with work. Considering that the tweets were selected using a set of work- or topic-related keywords, any analysis of word distribution would be skewed towards those keywords. Therefore, we randomly selected 100 tweets from each country, 50 with work-related keywords and 50 without. The instances are coded such that no tweet contained more than a single reference to any code. Therefore, a given tweet could reference multiple different codes, but a unique code can be referenced only once in each tweet. During thematic analysis, the codes were generated using the Grounded Theory approach (Bryant & Charmaz, 2007; Faggiolani, 2011; Halaweh, 2018; Lai, 2015). If we encountered a theme for which we had not created an appropriate code, we created a new one. Where appropriate, codes were created as child codes of previously created codes. Once the primary coder generated all codes, the secondary coder validated the codes and flagged disagreements. The disagreements were resolved over multiple iterations through discussions and code modifications.

**Sentiment Analysis**

**VADER**

VADER is a model for evaluating the sentiment of microblog posts, such as tweets, that uses a lexicon of human-reviewed terms and a set of semantic characteristics to measure the emotional character of posts (Hutto & Gilbert, 2014). We selected VADER as one of our computational methods due to its accessibility through common data sources. VADER was chosen because of its ease of use and accuracy in sentiment analysis, which is crucial for understanding the emotional landscape of academic librarian tweets.
analysis packages, ability to handle short, arbitrary texts, and ability to evaluate the sentiment of a text corpus without training data. VADER is an improvement upon earlier lexicon-based methods of assessing sentiments, such as Linguistic Enquiry and Word count (LIWC), in that it incorporates a set of rules regarding word sequence, negation, punctuation, and other factors that are commonly used to add emphasis or otherwise augment or diminish the sentiment of phrases. It is also popular among information and social science researchers (Bose et al., 2021; Cruz & Balahadia, 2022; Pano & Kashef, 2020).

Zero-Shot Learning (ZSL)

Recently, zero-shot learning has gained considerable attention among the scientific community because of its ability to generalize over unseen, unlabeled data. ZSL utilizes shared attributes or semantic embeddings (Palatucci et al., 2009) to identify new classes, leading to various methodological innovations. ZSL can be compared to unsupervised clustering approaches, except that it generates output labels without fine-tuning. Due to its ability to identify novel categories, ZSL has been applied for image classification (Akata et al., 2013), object recognition (Lampert et al., 2014; Socher et al., 2013), sentiment analysis (Yadav & Chakraborty, 2021), and action recognition (Liu et al., 2018). Some of the popular approaches are determining a compatibility function linking input instances with class embeddings (Akata et al., 2015), employing deep generative models (Verma et al., 2018), and utilizing graph convolutional networks (Wang et al., 2020). In recent studies, contrastive learning techniques have been used for zero-shot sentiment analysis, utilizing pre-trained language models. For zero-shot sentiment classification, the inherent semantic richness of natural language, along with the transferability of pre-trained language models like BERT (Devlin et al., 2018) and GPT (Radford et al., 2018), allows for the extraction of contextualized representations for previously unencountered sentiment classes.

In our work, we used ZSL to annotate the tweets with their respective sentiment labels. ZSL allowed us to overcome one major challenge of NLP research – the lack of human-annotated gold standard data. Our dataset was mostly unlabeled except for a small random sample we used for testing. The sentiment labels were positive, neutral, and negative. We used the pre-trained ‘facebook/bart-large-mnli’ model for our zero-shot model but did not fine-tune using our dataset. For evaluation purposes, two human coders annotated 100 random tweets. We also extracted 100 tweets for which the two models (Vader and ZSL) have maximum disagreements and reviewed them for accuracy.

RESULTS AND DISCUSSION

This section reports the results and answers the three research questions.

Predominant Themes in the Tweet Collection (answering RQ1)

In this section, we analyze the content of the tweet to investigate what academic librarians discuss on Twitter, in association with their employment and workplace-related keywords.

Most Frequent Words in the Tweet Collection

Analysis of tweets with keywords removed shows that the term “library” looms large in both the wordcloud of all words and those with keywords removed. After removing keywords, the word “thank” appeared most frequently in the wordcloud, reflecting the use of tweets to express gratitude and goodwill. Among keywords, “work” was the only one among the ten most frequently used words.

Thematic Analysis

Our thematic analysis revealed four major categories of themes: 1) Professional, 2) Personal, 3) Hobbies, Interests, and Recreational, and 4) Miscellaneous. The themes are summarized in Figure 3, with top-level themes in blue and the subcategories in yellow. Areas of each shape are proportional to the prevalence of a subcategory in the dataset.

![Figure 3. Distribution of Themes (Random Sample of 100 Tweets)](image)

Professional tweets constitute the most prevalent group of codes among the selection, with 159 references among the six selections. Subcategories of this group include Academic Libraries, Professional Development, Publishing, and
Thematic analysis revealed that tweets containing keywords are substantially more likely to refer to professional themes—lending support to our keyword frequency method as a decent means of identifying tweets relating to work and employment. Tweets from the United Kingdom are more likely to reference professional themes than those from the United States or Canada. Tweets from the UK that contain keywords are the most likely to reference professional themes, while tweets from the US that do not contain keywords are the least likely to reference professional themes.

The theme of burnout did not appear among the random sample of tweets selected for thematic analysis. A more comprehensive search of our collected tweets yielded only two tweets that explicitly referred to “burnout.” Furthermore, only one tweet in the dataset referred to “morale.” These findings do not cast doubt on the research conducted on these topics so much as they do the hypothesis that Twitter is a forum for discussions of these important topics.

**Country-specific Analysis for the US, Canada, and the UK (answering RQ2)**

The wordclouds in Figure 4 show the distribution of words excluding the work-related keywords in the tweet collection for the United States (Sample Size = 5885), Canada (Sample Size = 1010), and the United Kingdom (Sample Size = 2179). This unbalanced geographic distribution was a limitation of our data collection process.

![Word Clouds](image)

### Word Clouds of Country-specific Tweets with Keywords Removed

**United States**
Tweets from the United States comprised most of the dataset (5885 tweets out of 9821). As can be seen in the wordcloud for US tweets, the word “im” (“I’m” with the apostrophe removed - an artifact of our data cleaning process) was the most frequently used. This possibly reflects a tendency among US users to write tweets from the first-person perspective rather than on behalf of groups or institutions. In contrast to the data overall, words expressing gratitude, such as “thank,” appeared to be less prominent. Nevertheless, one word expressing a high degree of positivity, “love,” was among the most frequently used words.

**Canada**
Among the three countries represented in the dataset, the smallest number of tweets pertained to Canada (1010 of 9821). The words most frequently represented in the Canadian data deviated substantially from those in the data overall. The two most frequently used words in Canadian tweets, “ontario” and “hamilton,” are references to Canada’s largest province and a major city in that province. Given that a plurality of Canadians resides in Ontario, it is unsurprising that so many tweets mention it. However, names of places were not among the most frequently used terms in either the US or UK tweets. Interestingly, the word “library,” the most frequently used term in the dataset overall and among the most frequently used in both the US and UK subsets, was not among the ten most frequently used words in the Canadian data.

**United Kingdom**
Tweets from accounts based in the United Kingdom represented the second largest group in the dataset (2179 of 9821). Keywords related to work appeared in UK tweets with a frequency similar to the frequency with which they appeared in tweets from the US and Canada, with a few noteworthy differences. The term “hiring,” which appeared among the ten most frequently appearing keywords for the US and Canada, is not present among them in the UK data. With regard to non-keywords, the term “access” is the most frequently used term, followed by “library.” The terms “thank” and “thanks” are among the ten most frequent terms in the UK data, providing evidence that UK-based academic librarians may be somewhat more likely to use Twitter to express gratitude than other academic librarians.

**Distribution of Sentiment across Locations**
In Figure 5, we present the boxplots for the US, Canada, and UK subsets. Despite the broadly similar confidence levels of VADER and ZSL (0.82 and 0.77, respectively), the methods differed significantly in the actual labels applied to the tweets across the three countries. The VADER results are notable due to the overwhelming propensity of the classifier to label tweets as neutral in sentiment (see Figure 5). To compare countries based on sentiment, VADER is not reliable due to this flattening effect. The labels applied by ZSL, which more reliably distinguished
tweets as either positive or negative in sentiment, revealed that tweets in the United States and Canada had similar ratios of positive, negative, and neutral tweets. ZSL also highlighted that the set of tweets originating in the UK contained nearly twice as many positive tweets as negative tweets. Although ZSL performed better than VADER, it is not comparable with human evaluation. Also, the collection of tweets is not exhaustive. Therefore, further qualitative work is needed before making any broad generalizations.

Unsupervised Analysis of Tweet Sentiments (answering RQ3)

Performance of Unsupervised Prediction Models

To better understand which of the computational sentiment judging processes, VADER and ZSL, more closely corresponded to human judgments, we randomly selected 100 tweets from the dataset and had two human raters (researchers) assign sentiment labels (positive, neutral, or negative) to each of them. Following an initial round of human rating, we took a second pass through the tweets to reconcile our judgments. We calculated Cohen’s kappa – a measure of interrater agreement that accounts for the possibility of the agreement due to random chance, with 0 indicating no agreement and 1 indicating perfect agreement – between the human raters after each pass. After the second pass, the kappa statistic (see Table 1) revealed that raters 1 and 2 were in nearly perfect agreement, lending credence to the assumption that human raters could come to a consensus about the sentiment of the random tweets (McHugh, 2012). Finally, for the few tweets for which the differences between raters 1 and 2 were irreconcilable, we turned to a third human rater and regarded the label applied by rater 3 as authoritative. We created a composite set of human labels (the labels for which raters 1 and 2 agreed along with the labels of rater 3, where raters 1 and 2 could not agree) to serve as the ground truth against which we compared the VADER and ZSL labels. Using the gold-standard human annotations, we calculated the precision, recall, and f-1 scores of VADER and ZSL models (see Table 2).

<table>

<tr>
<th>Iterations</th>
<th>Interrater Agreement Between Human Raters 1 &amp; 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pass 1</td>
<td>0.55</td>
</tr>
<tr>
<td>Pass 2</td>
<td>0.83</td>
</tr>
</tbody>
</table>

Table 1. Inter Annotator Agreement for Randomly Sampled 100 Tweets

Overall, the judgments yielded by ZSL more closely resembled human judgments. Specifically, ZSL was more likely to apply the correct label to tweets that human raters judged to be negative or positive. However, VADER proved to be the more accurate judge of tweets that were neutral in sentiment, but only because it classified all but six tweets as neutral in sentiment (see Figure 6). While VADER performed abysmally on tweets human raters judged to be positive or negative, it did not demonstrate the apparent propensity of ZSL to place tweets into the binary categories of positive or negative. The performance of both models can be found in Table 2.

Disagreement Analysis - Comparing Models

In order to understand the degree of disagreement between VADER and ZSL, we calculated a “disagreement score” for those tweets for which the models selected different labels. For each tweet, both ZSL and VADER gave the confidence scores of the corresponding labels (positive, neutral, and negative), and the sentiment with the highest confidence score was assigned to each tweet instance. Then, for all tweets with conflicting sentiment assignments (where VADER and ZSL are not in agreement), we computed the disagreement scores as the sum of the ZSL and the VADER confidence scores. Therefore, tweets with opposite labels received a confidence score in the range of 0 to 2, with 2 indicating that each model had perfect confidence in the label it selected and yet was in disagreement. A
score around zero (0) would signify that the models differed in their judgment but were not confident in their predictions. For further analysis, we selected the top 100 tweets with the highest disagreement scores. Two human annotators rated the tweets with an agreement of 86% (86 instances out of 100). We evaluated both the VADER and ZSL performance over the 86 tweets for which human annotators agreed. ZSL predicted 63 of these 86 instances correctly (accuracy of 73.2%), while VADER predicted 21 instances correctly (accuracy of 24.4%). Once again, VADER predicted all these instances as neutral, while ZSL marked them as either positive or negative. Interestingly, ZSL exhibited a greater range of confidence scores (like humans) than VADER (which was confidently incorrect).

![Figure 6. Confusion Matrices for Zero-Shot Learning (ZSL) and VADER](image)

Next, we performed a qualitative analysis of the top disagreements. We picked instances where VADER and ZSL predicted the sentiment to be on the opposite end (positive and negative, with neutrals removed). The two computational processes were more likely to disagree on tweets that contained both highly positive and negative words or emojis. Often, such tweets expressed sarcasm, humor, or sympathy. Such tweets defy common notions of goodness, badness, or neutrality or else express one of those sentiments in recondite or ironic ways. For example, does the tweet “Ooof, hoping for the best.” express a positive or negative sentiment? On the one hand, the phrase “ooof” seems to be expressing shock or discomfort, while “hoping for the best” seems to express optimism and, perhaps, well wishes. In all cases of the most extreme disagreement, ZSL labeled the tweet as negative, while VADER labeled it positive. Multiple instances with conflicting sentiments contained only two words, which meant that the models had a small amount of text to analyze and derive a sentiment label. In the case of VADER, which uses a lexicon and a set of rules, one of the words strongly outweighed the valence of the other word.

**CONCLUSION**

We took a mixed methods approach to explore the behavior of academic librarians on Twitter and how their engagement and sentiments differed between the United States, Canada, and the United Kingdom. We had a special interest in observing the degree to which academic librarians in our dataset discussed issues relating to work, labor, and employment and how discussions of these issues differed between three countries with many cultural and linguistic similarities, but different institutional environments. To do this, we performed a word-frequency analysis of tweets from each country and a thematic analysis of random samples of tweets from each country. We also performed sentiment analysis of the dataset, labeling the sentiment content of tweets using two computational methods, VADER and Zero-Shot Learning, and discussed the advantage of ZSL in classifying the sentiment of academic librarians’ tweets. Employers and organizations could leverage such a sentiment analysis approach to assess certain workplace policies and their influence on employee satisfaction.

For our first research question, we found that expressions of gratitude are common in academic librarians’ tweets and that professional topics (encompassing subtopics such as academic libraries, work and employment, professional development, and publishing) were the largest categories represented in the random sample. This gives
us a better understanding of what can be learned about academic librarians from their Twitter usage. For the second research question, we found that academic librarians in the United States and Canada were more likely to discuss non-professional topics than those in the United Kingdom. Librarians in the UK were also more likely to express positive sentiments in their posts than in the US and Canada, which hints at differences in how librarians in the three different countries are socialized to regard social media.

To answer our third research question, we used a state-of-the-art approach for sentiment classification – Zero-Shot Learning (ZSL) – and compared the performance against an off-the-shelf classifier like VADER, commonly used by information and social scientists. One major methodological contribution of this research is that it highlights how we can develop accurate sentiment classifiers with minimal or no training data. Our evaluation suggested that ZSL significantly outperformed the lexicon-based VADER method by more often correctly classifying the sentiment content of tweets. The approach could be extended to other social media data where a faster turnaround time may be required, as is often experienced during disasters, medical emergencies, and important events. Our findings also suggest that the tweets in the United States and Canada had similar ratios of positive, negative, and neutral tweets, while tweets originating in the UK contained nearly twice as many positive tweets as negative tweets. This research raises interesting possibilities for future research on the content and sentiment of online communications by members of professional communities. We demonstrate that by incorporating state-of-the-art unsupervised models like ZSL, it is possible to outperform traditional libraries like VADER, especially when generating output labels for large volumes of data which are not annotated.

LIMITATIONS AND FUTURE WORK

One weakness of our research is the potential impact of the bandwagon effect on the data. While online behavior is often thought of as looser or less inhibited than face-to-face interaction, factors that researchers have identified as promoting disinhibition, especially dissociative anonymity, are inapplicable among the academic librarians we studied, who tended to eschew anonymity on Twitter (Suler, 2004). The bandwagon effect could manifest in two ways: self-censorship (refraining from speech an individual thinks may not be well-received by their social network) or engaging in speech that signals group belonging, which is not sincerely felt.

Self-censorship on social media has often been studied in authoritarian regimes where individuals may voluntarily restrict their posts to avoid state surveillance and repression (Bodrunova et al., 2021; Lee & Chan, 2009; Ong, 2021). It has also been studied in the context of hotly contested elections in democracies (Powers et al., 2019). However, studies of internal social media in workplaces have also demonstrated evidence of self-censorship by employees wanting to conform to workplace norms (Madsen & Verhoeven, 2016). Similarly, survey data of scientific researchers indicate the potential for a poor online reception to result in self-censorship (Väliverronen & Saikkonen, 2021). Social media accounts associated with their owners’ profession and place of work may also engage in a certain amount of self-censorship, even when posting outside the office or on topics not directly related to their professional expertise. We did not attempt to account for self-censorship in the data, and assumed that tweets reflected their authors’ authentic points of view. Concerning the bandwagon effect driving the types of content academic librarians choose to post, such behavior is analogous to the bandwagon effect in consumer behavior (Leibenstein, 1950). It is possible that, out of a desire to garner engagement, foster a closer connection with one or more individuals they follow, or acquire a reputation as an authority figure on a given topic, among other possible reasons, an academic librarian decides to post or re-tweet content. For our future work, assessing the impact of the bandwagon effect on tweet content would require marrying thematic analysis to network analysis to determine the degree to which thematic similarity is correlated with connections within a social network. The findings could be further bolstered by surveying academic librarians on Twitter to gauge their subjective motivations for or refraining from posting.

An additional limitation of the present study was the underrepresentation of UK and Canadian tweets relative to those from the United States. Future work should aim to collect more geographically balanced data. Finally, we were disappointed to find that discussions of burnout and shaky workplace morale, which have motivated so much other research in the LIS field, were largely absent from the data we collected. Again, we sense that it is likely that few librarians feel comfortable sharing thoughts on these topics in a public forum such as Twitter and that more research is needed to understand not only what librarians feel comfortable sharing on the platform but also what they feel is inappropriate or unwise to share. In light of Twitter’s recent change in leadership, it would be interesting to revisit the librarians sampled in this study to assess how their behavior may have changed.

A Guided Tour Study of the Untidy but Inspirational PIM of Visual Artists

Dinneen, Jesse David
Humboldt-Universität zu Berlin, Germany | jesse.dinneen@hu-berlin.de

ABSTRACT
While all individuals deal with increasingly large amounts of digital information in their everyday lives and professionally, prior works suggest visual artists have unique information management practices and challenges. This study therefore examined the personal information management (PIM) practices and challenges of six practising visual artists using guided tours and short interviews. It was found that the visual artists had some unique practices connected to their strong emphasis on serendipity, inspiration, and visual dimensions of information. Like non-artists, the participants faced challenges across all phases of PIM, chiefly an excess of information and fragmented organisation, and they found it especially hard to assess how personal and valuable their information could be. After characterising this rarely discussed PIM demographic, we draw on the findings to provide concrete recommendations for artists doing PIM, for information and cultural heritage institutions, and for designers of PIM software.

KEYWORDS
Personal information management; visual artists; guided tours; information behaviour; human-computer interaction

INTRODUCTION
Today individuals deal with increasingly large amounts of information (Vitale et al., 2020) including paper-based and digital personal information. This is also true for visual artists, defined here as professional creators of visual art (i.e. not of other art forms like music or dancing). Personal information management (PIM) examines how people keep, organise and re-find their personal information and has been described as "one of life’s essential skills" in today’s information society (Jones et al., 2017, p. 3584; Whittaker, 2011). The PIM of visual artists has only recently been examined in a small number of preliminary studies (reviewed below), which together suggest their practices and challenges may be unique and thus potentially elucidating for PIM research and tools more generally. It is also valuable to learn about how artists approach (or neglect) PIM and their struggles therein, because their personal information collections, if preserved, could become cultural heritage worth saving for future generations (Kralic et al., 2021; Post, 2017a).

The aim of this research is to discover more about the PIM of visual artists and the challenges they face regarding the management of their personal information. These insights might improve the visual artists' current day-to-day interactions with their personal information and address any PIM challenges they face, as well as guiding collaborations with memory institutions ultimately leading to the preservation of visual artists' personal information collections over the long-term. Additionally, the findings of this study can inform the development of PIM tools to match the requirements and practices of visual artists. The study in particular is concerned with the digital personal information of the participants that is related to their work as artists and that they manage on their computers, and seeks specifically to characterise their PIM practices and challenges (and especially their potential novelty).

As little is known about artists’ PIM, we employed an exploratory and qualitative approach, conducting interviews and guided tours with six practising visual artists with the goal to characterise their PIM and generate recommendations for individuals, information institutions, and PIM system designers and researchers.

LITERATURE REVIEW
Here we briefly review PIM practices and challenges before outlining the gaps in knowledge around artists’ PIM.

PIM and PIM practices -- PIM is "the practice and the study of the activities a person performs in order to acquire or create, store, organize, maintain, retrieve, use, and distribute information in each of its many forms... as needed to meet life’s many goals" (Jones et al., 2017) and today increasingly happens in the digital realm (Vitale et al., 2020). In the foundational PIM literature, both Jones (2007; Jones et al., 2017) and Whittaker (2011) propose a framework (or mode) for PIM activities describing a life-cycle of personal information, but whereas Whittaker (2011) names the three PIM stages keeping, managing and exploiting, Jones, (2007) calls them keeping, managing (or meta-level activities) and (re-)finding. It has been argued that these models are roughly equivalent because exploitation and (re-)finding are both describing how personal information can be retrieved and used (Dinneen & Julien, 2020). Since re-finding is less likely than exploiting to have an alternate interpretation in any given use and a narrower subset of management practices has been examined here, this study uses the terms keeping, organising and re-finding.
Although some PIM practices have been examined frequently (e.g. tagging, a kind of organising), there is no list of common PIM practices in the literature. This is perhaps understandable since PIM studies tend to focus on particular factors like emotions (Whittaker & Massey, 2020), formats (e.g. files; Dinneen & Julien, 2020), tasks (e.g. keeping; Vitale et al., 2018), tools (e.g. emails; Whittaker & Sidner, 1996) or demographic groups (e.g. knowledge workers; Alon et al., 2019). Reasons for this may include that PIM practices are determined by individual differences (Alon & Nachmias, 2020a; Boardman & Sasse, 2004), PIM practices are changing with the introduction of new technologies (Alon et al., 2019) and most PIM studies focus on particular aspects of PIM behaviour or specific practices (Alon & Nachmias, 2020b).

**PIM challenges** -- Not only is there generally more information available than ever before (Johnson, 2014), individuals also deal with large and growing amounts of personal information (Vitale et al., 2018). The accumulation of information makes all stages of PIM (selecting, organising and re-finding) more difficult and might lead individuals to feel stressed (Vitale et al., 2019). Determining the value of information items can be difficult (Whittaker, 2011) and individuals struggle to decide if they should keep or delete information (Boardman & Sasse, 2004; Vitale et al., 2018; Whittaker, 2011). This often leads to a tendency to keep information by default (Boardman & Sasse, 2004; Vitale et al., 2019), which in turn makes retrieving information more difficult and time consuming. If individuals do not have the time to process all the information they encounter or use it meaningfully, this experience is called information overload (Bawden & Robinson, 2020; Whittaker, 2011). Information overload can affect individuals negatively by deteriorating their health, making them less efficient, reducing their ability to make decisions, be productive, innovative and even creative (Bannon, 2006; Bawden & Robinson, 2020; Johnson, 2014).

Another aspect that makes the complex task of PIM difficult, especially in the digital realm, is that information can be experienced and stored on various devices as well as online platforms, thus forming ecosystems of personal information (Vertesi et al., 2016; Vitale et al., 2018). The phenomenon of storing information in various locations or applications, each using different organising schemes, is known as information fragmentation (Jones et al., 2017). Information fragmentation affects all three stages of PIM (keeping, organising, re-finding) and makes it harder for an individual to have an overview of their personal information (Jones et al., 2017; Vitale et al., 2018, 2019).

As individuals accumulate personal information throughout their lifetime, this information has to be managed not only in the short term, but also over long periods of time (Jones et al., 2016), including long-term project management (Copic Puchiar et al., 2016). Individuals keep personal information for the use beyond the immediate future (Bass, 2013) or to create a legacy (Kaye et al., 2006). There seems to be a tension between the increasing amounts of data that individuals keep (Vitale et al., 2019) and what they would like to share with future generations (Gulotta et al., 2013), ideally selecting only remarkable information to keep (Lindley et al., 2013; Vitale et al., 2019). Visual artists fall into one of the demographic groups whose personal collections might be valuable as cultural heritage and not only to the individuals personally (Krtalíč et al., 2021; Post, 2017a). Previous research investigated the personal collections and PIM behaviour of notable people, but this research did not focus on digital collections (Krtalíč et al., 2021). The personal collections of less well-known individuals, like emerging artists who might become famous or local artists, might equally be considered culturally significant in the future and thus should be kept (Post, 2017a). Knowledge about the PIM of visual artists can inform institutions that might potentially be interested in keeping this information, raise the awareness of artists regarding their own PIM practices and challenges and guide the future development of PIM tools for visual artists (Krtalíč et al., 2021; Post, 2017a).

**Visual artists and PIM** -- Although PIM tends to have an individual focus, PIM practices and challenges are often influenced by common demographic features, such as occupation, and such groups are therefore examined in PIM studies despite the usual focus on individuals. For example, PIM studies have examined teachers (Diekema & Olsen, 2014), knowledge workers (Alon et al., 2019) and immigrants (Krtalíč, 2021), among others. The demographic group of visual artists, however, has only been the focus of one recent study addressing the personal collections of writers and visual artists in New Zealand, which explored how they perceive the value of their personal collections, their collection management practices and challenges, and the influence these phenomena may have on the possible
future use of such collections (Krtalić & Dinneen, 2022). Among the findings were that the participants saw value in their personal collections and used idiosyncratic management practices (Krtalić & Dinneen, 2022).

The information behaviour of artists has been described as distinctly different from other demographic groups (Hemmig, 2008; Mason & Robinson, 2011). They were found to seek especially visual information for inspiration and use extremely idiosyncratic sources of inspiration, including intangible information (Hemmig, 2008, 2009; Mason & Robinson, 2011). Artists have been reported to potentially call anything a source of inspiration, often drawing on information sources that have no direct relationship to the art world (Hemmig, 2009; Mason & Robinson, 2011). Furthermore, they are described as information gatherers who use browsing to find information (Hemmig, 2008, 2009; Post, 2020). Browsing makes unintentional information encountering (serendipity) possible. Serendipity has been studied in information behaviour (Erdelez, 2005; Erdelez & Makri, 2020; Liu et al., 2022; Mason & Robinson, 2011) and, for example, as a design principle (Reviglio, 2019). Further, a connection between finding inspiration and serendipity has been made (Peterson, 2020).

Although not explicitly using a PIM perspective, a recent PhD thesis examined the value and management of digital information of visual artists in the UK, focusing on the wider context of what information practices are involved in art making and the value of digital information in artistic practice (Molloy, 2021). As might be expected, the use of digital information was found to be fundamental to contemporary art practices. However, the participants lacked the relevant digital skills and expertise, which were described as invisible skills and invisible labour (Molloy, 2021).

Previous research also examined the long-term preservation of new media artists and the collaboration between a local artist and an institution to preserve his personal information collection over the long term (Post, 2017b, 2017a). From these studies, we know that media artists keep original digital artworks and digital documentation of their artworks. They use their personal archives for various professional activities, including applying for grants, making portfolios or artist statements and addressing estate concerns. At the same time, new media artists believed that making artwork was more important than thinking about preserving it for future generations (Post, 2017b).

**Summary** -- Disparate studies have begun to indicate that artists’ PIM practices and challenges may be useful to learn about and support, but such phenomena have not been systematically investigated. Analysing the PIM of visual artists will help to understand how they keep, organise and use their personal information as well as what challenges they face. The importance of visual information and the heterogeneity of their information sources described above (Hemmig, 2009) might influence visual artists’ behaviour or require them to employ particular PIM practices. Previous research on visual artists gives almost no insight into the handling of contemporary, digital, PIM-related items and it has been noted that further research is needed to investigate the personal archives of artists (Post, 2017b). Beyond their use for the individuals themselves, the personal information collections of visual artists could potentially be valuable for others (Post, 2017a). Exploring visual artists' PIM practices and challenges thus has the potential to support artists and institutions in preserving personal information collections, raise artists' awareness regarding PIM, and inform the development of PIM tools.

**METHODOLOGY**

**Research objectives and questions**

Following the knowledge gaps identified above, the objective of this study is to examine the PIM practices of visual artists related to their work and identify what PIM-related challenges they may face. We thus pose the following research questions (RQs), with a specific concern for the digital personal information collections that relate to artists’ work (i.e. we examine no paper-based personal information nor information unrelated to artistic practice).

RQ1: Which PIM practices do visual artists use?

RQ2: What are PIM challenges for visual artists?

To answer the first question, it will be examined what PIM practices artists employ, and which of those are unique or common to non-artist PIM. To evaluate uniqueness, in lieu of an existing list of PIM practices, a list of known practices was compiled from existing literature; this list can be found in the Discussion section as codes (Practices shared by non-artists) in Table 3. Sources for the list included prior PIM publications that (a) give a comprehensive overview of PIM (Jones et al., 2017; Whittaker, 2011) or (b) collect and name a large number of practices regarding digital PIM (Alon et al., 2019; Alon & Nachmias, 2020b; Boardman & Sasse, 2004; Jones et al., 2015). Each practice was assigned to one of the three common PIM stages discussed above (keeping, organising, and re-finding).

**Data collection**

We employed a qualitative approach to identify possible practices and challenges and elicit further information about the relatively unknown phenomenon of artists’ PIM (Connaway & Radford, 2016).

**Sample and recruitment** -- A purposive sample of six participants was used in this study. Although non-probabilistic sampling often relies on data saturation to determine the necessary number of participants (Guest et al., 2006), it is
unlikely that data saturation would be attained in this study because of the nature of the participant group and of PIM itself; rather, the individualistic nature of PIM (Boardman & Sasse, 2004; Jones et al., 2015) and especially the uniqueness of artists with idiosyncratic information needs and types (Hemmig, 2009; Mason & Robinson, 2011) are among the study’s premises and are suggested by the research reviewed above. A sample size of six participants has been described as a conventional baseline for such studies (Helfferich, 2009, p.175) and recent meta-research indicates that in exploratory, qualitative studies "typically 6-7 interviews will capture the majority of themes" (Guest et al., 2020, p.13).

Participants were recruited through the authors’ connections to the local visual artist community (i.e., recruitment via gatekeeper). An important consequence was that some level of trust had already been established between the authors and the participants before the start of the guided tour, which is recommended (Thomson, 2018) since during guided tours participants’ private spaces and personal information are exposed. Participants were selected only if their primary profession is that of a practising visual artist (e.g. exhibiting and/or receiving grants) and they manage information themselves (e.g. without the help of an assistant). Although it was not a study goal to generalise the findings across all artists, variation was sought among participants practising different art forms (e.g. sculpture, drawing, painting, video) to avoid the findings being solely about practitioners of one art form and to instead enable examining a breadth of practices and challenges within the sample.

Participants -- A summary of the participants’ demographic and criteria-related data can be found in Table 1. All participants were working in Germany. The participants included three men, two women, and one non-binary person, each practising different art forms. All participants showed their laptops during the guided tour, with the exception of P1, who did not own a laptop and showed his desktop computer; all participants used MacOS.

Table 1. Summary of study participants.

Procedure -- The guided tour is a technique that has been applied to research in physical (Malone, 1983; Petrelli & Whittaker, 2010) and digital personal information spaces (Barreau, 1995; Boardman & Sasse, 2004; Vitale et al., 2018), wherein the participant leads the researcher through the physical or digital space in question while sharing thoughts and stories in a manner similar to the think-aloud protocol, thus leveraging a visual method (Hemmig, 2009) to elicit a description of the collection and related processes and perceptions (i.e. with the benefit of examples and not relying solely on memory) and allowing participants to show only what they wish (Thomson, 2018). The guided tours were conducted in October 2021 following a protocol and the guidelines of Thomson (2018; e.g. participants were assured their PIM would not be judged) and included only the digital spaces of participants’ desktop or laptop computers where personal materials related to their artistic work were stored. Two pre-tests suggested the approach was effective for collecting the necessary data and would take approximately 75 minutes per participant, which falls between the times reported in comparable guided tours (e.g. 45 minutes; Vitale et al., 2018, and 90 minutes; Bergman, 2013). Five of the guided tours were conducted in person and one remotely (i.e. with screensharing). As a guided tour generally reflects the current state of a participant’s personal information and, to some extent, their past practices, post-tour interviews were used to ask about the future of the collection. Sessions of one tour and interview each were video recorded and lasted between 47 minutes and 75 minutes.

Data analysis
The session recordings were transcribed and thematically analysed in MAXQDA Plus 2020 (20.4.1) until the themes below were identified (Braun & Clarke, 2006). Deductive codes (the practices and challenges collected during the literature review) and inductive codes (practices or challenges mentioned by participants but not found during the review, hereafter unique practices and challenges) were identified successively. The resulting themes are summarised with example codes in Table 2.
### RESULTS

**PIM practices of visual artists**

The PIM practices of the visual artists are described within three themes: *Keeping everything*, *Not tidying up* and *Using everything as inspiration*. The practices of individual participants were all very different from one another and consensus about any particular practice was rare. These cannot be fully reviewed here and instead will be summarised in favour of showing the overall trends.

*Keeping everything* -- The visual artists from this study created, received or collected digital information. Most of the documents, kept by the visual artists were self-created original artworks (P2, P5) like videos, documentary video- and audio-recordings or supportive material (all participants), especially digital reproductions of physical artworks. The digital reproductions were often compiled to serve as a basis to create various other types of documents (applications, portfolios, websites, newsletters, catalogues) or new artworks (books, films). The artists used and continuously accessed new and old digital materials to create these compilations. The participants mainly worked with images: *I operate with images pretty much all the time* (P1) and used images in many different formats, as each use case required different resolutions, file formats (e.g. RAW, tiff, jpg, psd) or different editing of the images. Especially P1 and P2 collected information extensively, mostly in the form of inspirational material from the web. Overall, 5 of the 6 participants preferred to keep digital information and avoided deletion even if the information was not useful. One participant even created an extra folder called "discarded" for materials that she had rejected in her selection process:

> if something is in there that is good then I select it and put it into another folder

(P6)

*Not tidying up* -- Neither computer desktops nor folders of the participants were organised clearly or consistently. All but one participant (P3) used a rather chaotic organising system: *It is just a huge chaos.* (P5). Five of the six did not use coherent naming schemes, nor clear folder structures. They either mixed different information together in one project folder, saved information items in the wrong folder or kept duplicates of the same information in many different places. Regarding folder structure, the most important practice of the participants was to sort information by project in an "art works" folder and an additional "grant applications" folder. Four participants keep all their projects (sometimes more than 50) sorted by name in a single folder. The participants did not use archive folders for older projects. Only P6 had a folder called "old applications" that could be described as an archive folder.

All of the participants mentioned that they felt that their desktop was untidy or referred to having the impression of it being chaotic or messy: *The desktop is ... kind of unsorted and there’s pretty much only stuff which I forgot about.* (P4) Figure 1 shows that P1 stored almost his entire information directly on the desktop, which he navigated like a map. The strategy of placing information in specific places on the desktop was also used by other participants.

*Sometimes there are these moments in which I start to arrange things towards the top or more into the middle and everything else to the bottom or the side, so that I can access certain folders very quickly for a meeting ...* (P2)

In contrast, as visible in Figure 1, P3 kept only current information on his desktop: *I have the ... desktop pretty empty actually... It just depends what I’m working on at the moment.* (P3), a practice that was also used by other participants.

participants: on the desktop I really have everything current, so, more or less current things that I kind of want to access quickly.  

Figure 1: Screenshots of the desktops of P1 (left), P3 (right). File names have been blurred.

Five of the six participants did not tidy up their digital personal information regularly. Two of the participants explained that they did not have the time or motivation to clean up: most of the time it’s like, that I, when I have finished something, then I’m just glad to be done and ... I don’t tidy up afterwards. It’s like after cooking, if I don't do the dishes. (P4) P5 noticed a difference between tidying up her artworks and "grant applications": like as if it would give me a better framework, if someone else directs me from the outside. So apparently, I am handling these applications more orderly than my artistic work. (P5)

To be able to access information more quickly, participants created reminders, most often in the form of screenshots: if I’m on the internet and I see things, I quickly take a screenshot, then they all accumulate in the top right corner. (P1) or by leaving windows open (used by half of the participants). Screenshots were also used by all artists for inspirational purposes: these are like stimulations or after research on certain materials, which I then save there. (P2) The screenshots were usually kept for their visual value and not as a reference to the original information, like bookmarks. Colour tags were used by all artists to mark selected images or to highlight projects that were recent, important, or in progress: the really important things, they then always have a colour like this. Or the things ... I access the most, have some colour and always a different one, so that, so that I can access them more quickly. (P6)

Using everything as inspiration -- The method preferred by participants for re-finding personal information on their computers was navigation and some even never used search (P4, P6), even if navigation was not successful immediately: if I had somehow been looking for these photos, I would have, I think, first gone here into the works and then here in [name of folder] ... they’re not in there, so I guess I have to look somewhere else. (P6) Four of the participants used the icons of the image preview to locate the correct file, stressing the role of their visual memory in the search process: if I see those in small, then I know right away which file it is. So, I know, okay, this is from that exhibition. (P1) Other participants used a mix of navigation and search. Some participants explicitly stated that instead of deliberately searching for information, they preferred to be inspired and enjoyed encountering information by chance as part of their creative process. P1 even saw his whole organising system as a way to accidentally discover information and regarded all his digital materials as potential sources of inspiration: And there is only this one connection with a very specific moment, with a very specific situation, an image and the connection to that text. And that is something that one has to rediscover first of all. (P1)

PIM challenges of visual artists
The PIM challenges of the visual artists are described within three themes: Keeping too much information, Allowing too much chaos and (Future) value of information.

Keeping too much information -- Four of the six participants stored large amounts of digital personal information. They were also aware that the accumulation of information was problematic, yet they found it difficult to delete anything: it’s always like that, things easily come to you, but then then it's difficult to let them go. (P4) Accumulating too much information was overwhelming for the participants: this potentially available material, I mean, it’s also totally overwhelming. (P1) One participant imagined that even without adding any new material, he would already have enough information to work with it for "years and decades" (P1). On the other hand, keeping a lot of clutter prevented the artists from concentrating on their tasks: and that’s why I would like to leave behind intermediary steps or bad quality and so on, to be able to concentrate better, so that I am not as distracted from what is essential. (P4)

Allowing too much chaos -- Information fragmentation occurred across devices, platforms, project spaces, formats and versions and affected participants to differing degrees as well as provoking negative emotional responses. Different versions of information items were kept abundantly by participants and versions were often hard to distinguish from duplicates: First of all, there are two different sizes, then I updated them because new ones were added ... there are ... different versions of the identical looking portfolio. (P1) The final versions of documents were
usually not marked and therefore could not be found easily. One participant (P2) reported that keeping her information in disorder was making her anxious and scared: There is just such a huge chaos and I’m more scared of that. (P5) Not finding information items could be very frustrating for the artists and caused many negative emotions or confusion: Some things I can’t find again immediately, then I have to look for a while... that’s more annoying. (P1) All of the artists expressed (mostly implicitly) that they thought that there was a right way to do PIM. Usually, they implied that tidiness would be more acceptable. As a result, participants felt bad and judged themselves for not being on top of things, not tidying up or doing PIM ‘wrong’: well, look, actually this is also totally idiotic... which is completely stupid. (P5) Half of the participants felt embarrassed towards the interviewer for being messy, as P1 expressed: it is already quite an effort to bring myself to show it like this. (P1)

The (future) value of information -- Five of the six participants did not know if any of the information they kept was even valuable at all or which information could be valuable: I think one would simply have to look at it all, as in: What is there? ... What is even relevant? ... What will even become relevant again? (P5) Some of the visual artists (P1, P2) even found it presumptuous to claim that their own digital work would be important enough to be kept as a legacy: it seems that for me it has some sort of ... relevance. But that doesn’t automatically mean that it is somehow relevant to somebody else. (P1) Putting personal collections into order was seen as a prerequisite to making them accessible to others: to have some sort of order in there, so that it is accessible for other people. (P5) Identity construction and sentimental reasons were not mentioned by the artists as being important aspects of their digital personal information. Most prevalent among the participants was a practical approach of keeping information to "find it later" (Kaye et al., 2006). Thus, (long-term) preservation was not a pressing concern for the participants: it’s only really for now. So, I don’t think about what it will look like in the long term. (P6)

DISCUSSION
RQ1: Which PIM practices do visual artists use?
The visual artists in this study used many common PIM practices and also employed several unique PIM practices that have not previously been described in the literature. As could be expected, many of these unique practices are visual. Another finding that stands out is that some of the participants enjoyed discovering their personal information serendipitously. Table 3 summarises which common PIM practices were applied by the visual artists and Table 4 shows their unique PIM practices. Each is discussed below.

Table 3. Common practices used by the visual artists.

Common practices -- The keeping activities of the visual artists could generally be described as "keep everything," as they rarely deleted information even if it was not useful, which is common for individuals (Sweeten et al., 2018; Vitale et al., 2018; Whittaker, 2011). Most of the personal information examined were self-created images. The organisation of personal information on their computer desktops and in folders was mostly chaotic; participants, for example, did not tidy up their desktops or placed all projects in a single folder in a flat hierarchy, which is atypical but nonetheless done by some non-artists. Organising systems were used inconsistently and the personal information was not tidied up frequently, adding further clutter and making it hard to re-find information. The preference for re-finding files by navigating to them (e.g. rather than using desktop search) is consistent with previous studies (Bergman, 2013; Dinneen & Julien, 2020; Malone, 1983).

Unique practices -- In total eight unique practices not yet observed in the reviewed PIM literature, were identified as being performed by the visual artists, as shown in Table 4. The unique practices were observed in all three PIM stages (keeping, organising, re-finding) and were all widely used by the participants.
Perhaps unsurprisingly, many of the practices unique to visual artists were visual in nature or concerned images specifically. For example, rather than keeping old versions or reproductions purely for documentation purposes, as individuals concerned with long-term preservation of personal collections might do (Krtalíć et al., 2021), the artists re-use the items in as inspiration for new projects. This is arguably a visual version of behaviour observed in teachers who re-use content from their personal collections when creating new material (e.g. lesson plans; Diekema & Olsen, 2011). Some of the artists used their computer desktop like a map, organising files and folders visually in certain areas of the desktop. We know that individuals keep large amounts of images in personal file collections (Dinneen & Julien, 2019), but not necessarily how they are organised and used. Using the desktop like a map also served the participants to re-find information using their visual memory.

The use of web-content by artists has been described previously (Mason & Robinson, 2011; Robinson, 2014), but not the specific use of screenshots as reminders or for inspiration. The visual artists also used colour tags as reminders. Instead of ascribing a meaning to a particular colour, they just used the colour to draw attention to a particular file or folder. For sure, many individuals besides visual artists use colour tags, but this practice has not explicitly been studied in the PIM research. The visual reminders like screenshots and colour tags also functioned as visual shortcuts to re-find information. Visual memory was also used by looking at preview images to identify a particular version of a film or image, a behaviour Bergman (2013) also observed in a graphic designer.

The visual artists regarded their personal information as potential material for inspiration, confirming Hemmig (2009). Some further exploited this by using serendipitous discovery (Erdelez, 2005) within their digital personal information collections instead of searching for particular information. The importance of serendipity has been recognised in the design of information architectures (Reviglio, 2019), but to our knowledge, the accidental encounter of information has not been connected to PIM practices or tools. While serendipitous discovery may be distracting or inefficient during known-item retrievals, it could also be more rewarding or inspiring (Mason & Robinson, 2011; Reviglio, 2019). Perhaps there is a relationship between the preference for serendipity, not deleting personal information, and the unstructured way of keeping artistic projects, thus giving the artists the opportunity to be surprised and inspired by their personal information in their creative process.

**RQ2: What are PIM challenges for visual artists?**

The challenges the visual artists faced were all common challenges and no unique challenges were identified. Most challenges were experienced by all of the participants and were related to information overload, information fragmentation, and determining the (future) value of the personal information.

*Overload and fragmentation* -- The increasing complexity of PIM and the resulting challenges have been remarked upon in the PIM literature (Alon et al., 2019). In contrast to knowledge workers, however, the visual artists who participated in this study did not employ any high-level strategies to deal with these challenges. Instead, most of them rather lost their motivation to engage in any PIM activities. Both information overload (Bawden & Robinson, 2020; Jones et al., 2017; Whittaker, 2011) and information fragmentation (Jones et al., 2017; Vertesi et al., 2016; Vitale et al., 2018, 2019) are common PIM challenges and were experienced to varying degrees by all artists. The participants collected large amounts of digital personal information and did not tidy up their information spaces regularly or consistently, as they perceived PIM activities to be a waste of time. Thus, they kept information (mostly images) fragmented across versions, formats and duplicates (Jones et al., 2017; Vitale et al., 2018, 2019) which also made it difficult and time-consuming to re-find information (Whittaker, 2011). Due to information overload, the participants found it hard to make decisions or concentrate and it caused them to feel overwhelmed, anxious, frustrated or lead to information avoidance, which is common (Bawden & Robinson, 2020). Additionally, the participants all expressed feeling bad about their PIM practices and judged themselves for not "doing it right" (Vertesi et al., 2016). Previous literature describes the tension the visual artists felt between actual and ideal PIM behaviour as a common challenge (Alon & Nachmias, 2020b).

Table 4. Unique practices used by the visual artists.
The (future) value of personal digital information -- The greatest struggle the visual artists from this study faced was determining the value of their digital personal information, which has been described as a common challenge (Whittaker, 2011). The main reason participants gave for keeping information was for future use, but the way they organised it made "finding it later" (Kaye et al., 2006) difficult. Especially the idea of "building a legacy" or estate (Kaye et al., 2006) was a challenging topic for the visual artists, as they did not believe that what and how they were currently storing their digital information would be accessible or valuable to other people. This finding is surprising because previous studies found that visual artists and writers see the long- and short-term value of their personal collections for themselves and for society (Krtalíč & Dinneen, 2022) and collections in the family context are valued as records, evidence of an individual's identity and personality and their broader societal value (Krtalíč et al., 2021). It would thus seem appropriate that artists should value the artworks they create and the processes around it.

Equally surprising is the fact that the visual artists hardly reported any personal or emotional involvement with their digital information. The literature, however, suggests that digital possessions are regarded as part of one's identity (Chen et al., 2021; Cushing, 2011; Kaye et al., 2006). Interestingly, leaving collections uncurated has been described as one reason why individuals would not view them as part of their identity and self-representation towards themselves (Odom et al., 2014) or others (Krtalíč et al., 2021). Additionally, digital information, compared to physical information, may seem less unique and thus less valuable to an individual (Odom et al., 2014). This has been attributed to the "spacelessness" (collections are physically not visible) of digital information (Odom et al., 2014). As the collections become less remarkable (Lindley et al., 2013) it is undesirable to share them with future generations (Gulotta et al., 2013). This behaviour and rationale were observed in the visual artists, endangering their personal information to be lost, even though it might contain valuable insights about the way artists work today, their creative processes or actual digital artworks that should be preserved as part of our cultural heritage.

This would confirm, that the way visual artists approach PIM affects how their personal information is valued (Post, 2017a). If the visual artists were to recognise the uniqueness and broader societal significance in terms of describing "time, place, and events" (Krtalíč et al., 2021, p. 170), it could potentially impact the value that they assign to their personal information. This highlights the importance of the artists themselves understanding how essential their PIM practices are in creating valuable information collections for themselves and for others. Molloy, (2021) suggests that this would require a greater appreciation of digital artistic practices in society at large, making this labour visible, as well as close collaboration between visual artists, memory institutions and LIS professionals in these matters.

**Recommendations**

Though the results of this study must be interpreted in their narrow context (see Limitations, below), they nonetheless suggest artists may need help selecting relevant information and deleting information to create personal digital collections that are more valuable for themselves and for others. They also seem to need support organising their personal information in a more structured way, and visually, to create a greater accessibility. The possibility of serendipitous discovery, which they favour, should also be taken into account. Addressing these areas would make the PIM practices of visual artists more efficient and consequently reduce their PIM challenges, including determining the value of their personal information and thus reduce the potential loss of important cultural heritage materials. The recommendations aim to address these concerns.

**Recommendations for artists --** Make tough saving decisions (Alon et al., 2019) and delete more information to make personal information collections smaller and therefore more personal, more accessible and more valuable for the artists themselves and for others and to avoid information overload. To help during the selection process, each project could be sorted into two folders with core and supportive information (Copic Pucihar et al., 2016).

**Recommendations for LIS professionals and cultural heritage institutions --** Build educational programs for visual artists that cover PIM topics related to digital information, making research more visible and accessible (Molloy, 2021; Post, 2017b). Offer these courses at art schools, institutions that publicly call for submissions or offer grants to visual artists (as these require applications in digital formats) and professional training programs (e.g. in Berlin the Goldrausch project for women artists, https://goldrausch.org/en/, currently providing some technical guidance for making artist websites but no input regarding PIM). This will firstly help provide a platform where artists can exchange their PIM experiences, expelling insecurities towards their own PIM style, or find new PIM practices suitable to their working environment. Secondly, it will share recommendations from PIM research about organising collections (Jones et al., 2015) and the importance of deleting (Hellmich & Dinneen, 2022).

**Recommendations for PIM tool developers --** Visual artists use screenshots as reminders and icons to re-find information. Therefore, support the flexible use of images in PIM tools, for example by allowing image view of images from several folders simultaneously, making screenshots searchable (visually, e.g. by colour, motif, or reverse image search), and including them in the image manager by default. Support serendipitous discovery of information by (e.g.) selecting and displaying a certain number of random images from the personal information...
collection or finding a complementary accidental image to a selected one. This could include drawing data from information resources commonly used in creative tasks (Li et al., 2022).

Besides the practical advantages of these proposals, it is advisable not to force tidiness upon visual artists nor reinforce the social stigma that sometimes exists around chaos and clutter. As Copic Pucihar et al. (2016) pointed out, messiness will not just disappear; it is part of PIM and especially visual artists seem to embrace and somewhat utilise it. Some enjoy being surprised by unexpected encounters and inspiration cannot be planned in advance. It thus seems promising to utilise this phenomenon to create PIM tools that support the creative process and help the artists with the PIM challenges they currently face. This will make it easier for visual artists to keep, organise and re-find digital information in the future and preserve their valuable digital material as cultural heritage.

Limitations
The main limitation of this study was the small and geographically narrow sample: despite their artistic variety, all six participants were from one region of one country. Thus, soundly interpreting and using the results requires considering that limited sample and that the findings may not generalise. While generalisability was not the study's goal, it is possible that further unique practices and challenges exist, and that other kinds of artists (e.g. performance) have vastly different PIM practices and challenges from the usual demographics studied. It would therefore be desirable to extend the current study to additional participants or recruit participants with different artistic practices, and from non-German and non-European backgrounds. For example, a more diverse sample could be recruited through professional associations or artists organisations (Molloy, 2021). There was also some inherent subjectivity in the identification and naming of the themes (Table 2), which were derived by a single coder and thus may not be fully replicable (however, that the themes align well with the typical PIM categories of keeping, organising, and re-finding suggests they are broadly reasonable). In future studies, using multiple coders would be preferable. Further, all participants used MacOS; while in some regions it is common for artists to use Apple computers, the software used may have an effect on their practices (Dinneen & Frissen, 2020). Finally, this study only investigated local digital collections shared by the artists and predominantly computer files (e.g. rather than email), so the role of additional digital and physical formats in visual artists’ PIM remains unclear.

CONCLUSION
This study investigated the PIM of visual artists regarding digital personal information that is related to their work and generated a list of digital PIM practices that may be used in future PIM studies. Using the method of the guided tour, data was collected by observing the artists navigate their personal information on their computers. The aim of the study was to gain more knowledge about the PIM of visual artists in the digital realm and the challenges they faced with this. The first research question asked what PIM practices the visual artists use and the second question what challenges they face. It was found that visual artists use common and unique PIM practices, but that they only face common PIM challenges. The unique PIM practices of visual artists included many visual practices. Keeping large amounts of information mostly unorganised could lead to many challenges that were experienced in all three stages of PIM activities (keeping, organising and re-finding), but was also used by some visual artists to make serendipitous discoveries. A major challenge for the visual artists was to determine what information would be valuable in the future. The results informed concrete recommendations for artists, memory institutions and PIM software developers.

This research contributed to the field of PIM by examining the previously understudied demographic group of visual artists. Studying the PIM of visual artists can, first of all, help to set up guidelines or workshops for this particular group, guiding their everyday interactions with their personal information related to their work as visual artists and secondly, guide artists and institutions alike to collaborate on finding appropriate ways of ensuring the (long-term) preservation of valuable personal information of the visual artists to help create their estates and legacies. Finally, the findings of this study can also contribute to the creation of new PIM tools that facilitate the keeping, organising and re-finding of digital personal information for visual artists so that they would be less burdened by its complexity and challenges. All these individual actions together can help to keep the personal collections as cultural heritage and be able to use them in the future.

Future research could examine the PIM of visual artists more holistically, including their paper-based personal information, as well as how visual artists share their information, how they use social media and how they collaborate with others. Additionally, the PIM of visual artists should be studied over the long term to gain more insights into long-term practices, challenges and the visual artists' attitudes towards their digital legacies, including the relationship to their identity. Such insights should enable improved or novel systems and services (Kljun et al., 2015) benefiting visual artists, cultural heritage institutions, and their future work together.

ABSTRACT
In response to the global disaster of COVID-19, every country has implemented various policies. China, as a developing country, has issued policies to combat COVID-19 that could serve as a reference for future pandemic prevention and control efforts, and may offer lessons for national governance. This paper employs bibliometric methods, text mining, and network analysis to mine and characterize the evolution of China's policies against COVID-19. Specifically, we extract policy targets and identify the policy tools from each policy, cross-compare the policy tools used for different policy targets, and characterize their evolution during the pandemic. Our findings show that policy targets have shifted over different stages to balance epidemic prevention with economic development. We also identify several shortcomings in distribution and utilization of policy tools. To improve policy implementation, it is crucial to align policy targets with appropriate policy tools and ensure a balanced and functional approach to policy implementation.

KEYWORDS
COVID-19 Prevention & Control Policy; Policy Document Mining; Policy Target; Policy Tools; Policiometrics

INTRODUCTION
Since the outbreak of COVID-19 in December 2019, it has had a seismic impact on the world. However, the impact has varied across different countries due to the diverse policies implemented to cope with the mutation of the virus, economic challenges, and the impact on the public (Dewi et al., 2020). Some countries have adopted strict measures to control the spread of COVID-19, while others have pursued herd immunity. These diverse policies have resulted in varying numbers of deaths and economic losses. While no country can be considered a perfect example, it is crucial to examine and analyze their policies in order to draw lessons for future national governance in the face of disasters like this.

China, being a developing country with a population of over 1.4 billion, has faced significant challenges and pressure in dealing with the COVID-19 epidemic due to limited medical resources. The Chinese government has implemented policies such as "Pandemic Lockdown" or "Dynamic Cleaning" at both the central and local levels, and the pandemic has persisted for three years in China. In November 2022, the number of the nucleic acid testing positives increase rapidly again in China. However, in December 2022, the Chinese government issued new policies regarding COVID-19, including the cancellation of nucleic acid testing as the only green pass for the public during the three-year period. This has led the public to perceive that the Chinese government has ended all prevention and control policies against COVID-19. Despite China's unique population characteristics, medical conditions, economic situation, and governance structure, which differ from developed countries, its policies in response to COVID-19 can provide valuable references for other developing countries around the world and may offer insights and lessons for future pandemic prevention and control efforts.

Therefore, in this study, our focus is to analyze the policies issued by the Chinese government during the COVID-19 pandemic. Instead of qualitative analysis of policy influence (whether the policies are better or worse) (Zhu et al., 2022), we employ text mining and network analysis techniques to quantitatively visualize the evolution of China's policies against COVID-19. We specifically examine the policy targets and policy tools, which are the two main components of policies. Policy targets represent the policymakers' intentions in textual form, while policy tools are the political actions and behavioral approaches employed to achieve the policy targets (Huang et al., 2018). Policy tools serve as measures to facilitate the attainment of policy targets and form the core contents of policies. Hence, we aim to analyze the evolution of China's policies from the perspectives of policy targets and policy tools.

RELATED WORKS
Policy Document Mining
Policy documents serve as carriers of policy and play a crucial role in governance and blueprint planning. Scholars use policy documents as a means to explore policy contents and policy processes (Wu, 2019). Quantitative research or mining of policy documents has emerged as a new direction in public policy studies (Huang et al., 2015). However, policy document mining is distinct from traditional scientific text mining, such as papers and patents, as...
accurately mining the content of policy text using bibliometric methods can be challenging (Huang et al., 2021). Previous research has mainly focused on policy topic mining, policy issue ministry network analysis, policy diffusion, policy tool/instrument analysis, among others.

Policy target and policy tool are also two crucial domains for policy document mining. However, there is limited quantitative research on policies against COVID-19 from the perspectives of policy target and policy tool, despite some exploration of COVID-19 policies. For instance, Wang (2021) assessed the impact of national culture and government policies on social distancing measures to combat COVID-19 and found that government stringency had a larger impact on social distancing. Zhu et al. (2022) analyzed the specific policy tools used in different periods of China's COVID-19 pandemic, but lacked deep quantitative statistics on different policy tools. Therefore, in this study, we employ text mining methods to extract policy targets and identify policy tools from policy documents and utilize quantitative analysis methods to explore the evolution of China's policies against COVID-19.

**Policy Target**

Policy targets are fundamental elements of policy documents that articulate the purpose and intention of policy-making. They are crucial for improving the implementation of policy actions. Relying solely on long-term targets makes it challenging to recognize and support early contributions, resulting in less effort being dedicated to the initial actions necessary for achieving long-term change (Lester & Neuhoff, 2009). Therefore, it is essential to have a mix of long-term, short-term, and specific policy targets to address policy issues effectively. In this case, the policy target cannot be summed up in one or two simple words and phrases. And, policy targets are shaped by the dynamic characteristics of the policy context and evolve with time and situation. Hence, timely and automated extraction of policy targets from policy documents is crucial for policy analysis and supervision.

The extraction and analysis of policy targets can unveil critical insights into the policy design and implementation process (Yang & Huang, 2022). For instance, Huang et al. (2018) proposed a bibliometric method to detect changes in policy targets and analyze the core policy targets in different time periods of China's nuclear energy policies. Yang et al. (2020) employed China's information technology policies as an example, constructing policy target keyword co-occurrence networks for discrete time periods to analyze the evolution of policy targets. Leveraging policy documents, the extraction and analysis of policy targets can facilitate the public's understanding of policy in a more direct and accessible manner.

For COVID-19 policies, policy targets pertain to the direction of prevention and control. If all policies against COVID-19 solely focus on achieving "Zero Clearing" without considering economic losses and pressures, then the policy targets must exclusively focus on prevention and control. The policy targets of Chinese policies against COVID-19 will directly and objectively reveal the purpose and intention of the Chinese government. Therefore, in this study, we aim to extract policy targets from policy documents to shed light on the Chinese government's thinking and considerations in their policies.

**Policy Tool**

Policy tools, also known as policy instruments, are instruments designed to encourage or enable people to take actions they might not have otherwise taken, or to overcome obstacles to policy-relevant actions (Schneider & Ingram, 1990). Policy tools have been an important dimension of exploration and promotion of policies, as exemplified by studies such as Xu et al. (2022), which investigated the relationship between environmental policy tools and economic development, examined the mediating effect of public health. Chai et al. (2020) also examined the structure and function of China's environmental policy based on policy tool theory. One of the most fundamental and significant aspects of policy tools research is the classification of policy tools, namely how to identify the category of policy tools used in various policy contexts.

Various scholars have proposed classification frameworks for policy tools over the years. For instance, Rothwell and Zegveld (1981) summarized 12 specific categories of policy tools, which they further grouped into three broad categories: supply-oriented policy tools, environmental oriented policy tools, and demand-oriented policy tools (Rothwell & Zegveld, 1985). Howlett et al. (2009) proposed three broad categories: command control tools, economic incentive tools, and social autonomy tools, along with eight specific categories. Bemelmans et al. (2011) summarized three categories: carrots, sticks, and sermons. Despite the passage of more than 40 years, the policy tool classification framework put forward by Rothwell and Zegveld remains the most widely used framework and has been applied in various domains (Huang et al., 2018; Qin et al., 2020; Kuo & Shyu, 2021; Zhu et al., 2022).

In this study, we employ an improved classification framework based on Rothwell and Zegveld's framework, derived from classical and recent research on policy tools, as shown in Table 1.

**RESEARCH DESIGN AND METHODOLOGY**

The key steps of our research design and methodology are outlined in Figure 1, as follows:

**Data Collection**

The policy documents pertaining to COVID-19 were collected from the PKULaw database, which is a highly authoritative and comprehensive legal database in China. Within this database, a special sub-database dedicated to "epidemic prevention & control" was utilized as an example. To ensure the representativeness and validity of the policy sample, only national policies issued by the central government or its direct agencies were considered. The policies included in the study were limited to those that published between December 27, 2019 and September 10, 2022, in order to ensure that the data specifically pertained to COVID-19 and its prevention & control measures.

The collected data then underwent a manual screening process based on the following criteria: (1) The policy document had to be in the form of a law, regulation, circular, or other official document representing government policy. (2) The main content of the policy had to be closely related to COVID-19. Following the screening process, a total of 1154 policy documents were obtained. According to the publication "Fighting COVID-19 China in Action" by the State Council Information Office of the People's Republic of China, the COVID-19 epidemic is categorized into four distinct temporal stages known as "stage 1", "stage 2", "stage 3", and "stage 4". Table 2 provides a detailed overview of these stages and the distribution of China's policy against COVID-19.
## Policy Targets Extraction

The "policy target" refers to the objective and intent behind the policy-making action, that is, the main problem that the policy aims to address. Policy targets are often implicit and difficult to discern. In order to address this issue, we utilize a policy target identification procedure (Yang et al., 2020), which leverages natural language processing methods and regular expressions. The procedure is outlined as follows:

1. First, the introductory paragraph of each policy document is located. The end of the introductory paragraph is determined by identifying the appearance of structures such as "ࠋ" or "㸸" in the policy text.

2. Second, policy targets in the introductory paragraphs are identified based on a verb/noun thesaurus constructed from common policy expressions. In Chinese policy document, policy targets are often expressed in the form of "in order to + verb + noun phrase". If this specific structure is identified and the words in the structure belong to the verb/noun thesaurus, which was pre-constructed using expert knowledge and extensive browsing of policy texts, it can be determined that a policy target has been identified. A partial summary of the "verb/noun thesaurus" is provided in Table 3. For the small number of policy texts for which the policy target could not be successfully extracted, manual reading was employed for additional extraction.

<table>
<thead>
<tr>
<th>verb</th>
<th>noun</th>
</tr>
</thead>
<tbody>
<tr>
<td>implement, provide, reduce, carry out, safeguard, maintain, promote, increase, support, strengthen, protect, curb, win, mitigate, improve, accelerate, enhance, promote, cope, encourage, guide, strengthen, play, help, establish, help, raise, reduce, regulate, prevent, control, simplify</td>
<td>spirit, deployment, service, risk, thought, work, principle, safety, stability, development, requirement, strength, recovery, management, health, instruction, supply, momentum, war, prevention, control, burden, integrity, progress, construction, capacity, guarantee, resumption, impact, resumption, epidemic, initiative</td>
</tr>
</tbody>
</table>

Table 3. Verb/noun thesaurus(partial)

(3) Clean the policy targets extracted initially, including removing stop words, and merging synonymous terms, etc;

(4) Identify the core terms in policy targets based on term clustering. To do this, we used TF-IDF to perform term clustering on the cleaned policy targets, which resulted in a set of words/phrases. The clustering results were then manually reviewed and modified, and core terms were abstracted from each set of words/phrases. These core terms served as the final policy target keywords. The TF-IDF weight was calculated as Expression (1) and (2), where $TF(t, d)$ represents the frequency of term $t$ in document $d$, and $IDF(t)$ represents the inverse document frequency, which was used to determine the importance of term $t$ in expressing a semantic dimension.

$$TF - IDF(t, d) = TF(t, d) \times IDF(t) \quad \text{(1)}$$

$$IDF(t) = \frac{\log \text{Total number of documents containing } t}{\text{Number of documents containing } t + 1} \quad \text{(2)}$$

After extracting the policy target keywords, we constructed policy target keyword co-occurrence networks and identified the core policy target keywords based on eigenvector centrality. Eigenvector centrality is a technique used to compute the significance of a node in a social network. It is based on the PageRank algorithm, with the objective of evaluating the performance of a node based on the impact of its neighbors. The mathematical basis for this method is the eigenvalue and eigenvector, it is defined as Expression (3), where $P(v)$ is the set of neighbors of node $v$, $\lambda$ is a constant representing the eigenvalue, $Adv$, $k$ is the adjacency value between node $v$ and $k$.

$$E_v = \frac{1}{\lambda} \sum_{k \in P(v)} E_k = \frac{1}{\lambda} \sum_{k \in P(v)} Adv_{v,k} E_k$$

(3)

## Policy Tools Identification

In the process of policymaking, policy documents often contain various policy tools. It’s challenging to identify them accurately. So we utilized a trained policy tool classification model based on the classification framework shown in Table 1. This model consists of pretrained WordBERT-ZH and BiLSTM. WordBERT-ZH is an improved
version of BERT specifically designed for Chinese text classification (Feng et al., 2022). The BiLSTM acts as a classifier to map the relationship between the embedding of policy text and the policy tool categories.

This policy tool classification model was trained on 8910 manually labeled samples derived from digital economic policies and data governance policies by the authors, making it the most accurate policy tool automatic classification model for Chinese policies (Huo et al., 2023). To ensure and improve the accuracy of this new dataset, we followed the active learning theory and added manually labeled samples derived from COVID-19 policies. Active learning is a mechanism that reduces the need for human annotation in training datasets and selects the most informative cases to achieve better performance compared to passive supervised learning algorithms (Figueroa et al., 2012). It has been successfully applied in various domains, such as text classification, image classification, etc. (De et al., 2021).

The identification of policy tools is carried out through the following steps:

1. First, we treat each policy paragraph as one policy unit, as considering one paragraph as one policy unit ensures that the statistics about policy tools are comparable and maintains semantic integrity, following the classical process of policy unit standardization (Lu et al., 2022). We then divide all policy documents into policy units, resulting in 8910 policy units related to COVID-19 policies.

2. Second, based on the model trained on digital economic policy and data governance policy, we classify the policy tools for each policy unit from the COVID-19 policy. To test the accuracy of the classification, we randomly selected 100 policy units and assigned a domain expert proficient in policy tool classification to independently encode them manually. By comparing the results of the model encoding and the manual encoding, we calculated Holsti's consistency percentage to assess the reliability of the model. The formula to calculate Holsti's consistency percentage is as Expression (4), Where M represents the number of codes that are completely the same in two encodings, and N1 and N2 represent the number of codes in the two encodings, respectively.

   \[ \text{reliability} = \frac{2M}{N_1 + N_2} \]  

(3) Finally, we optimized the classification according to the theory of active learning. As shown in Figure 2, we first checked the results of the policy tool classification model. If the accuracy of a certain category is not satisfactory, indicating that it is difficult to classify, we added more labeled samples to create a new training dataset for these categories with low performance. We then trained the model with this new dataset and tested the results again. After 9 rounds of coding and supplementing the training dataset, the final reliability of the first coding result reached 90%, meeting the reliability requirements. In total, we identified 8517 policy tool items from the COVID-19 policies.

**EVOLUTION ANALYSIS OF CHINA’S POLICY AGAINST COVID-19**

**The Evolution of Policy Targets**

Using the methodology of text mining and network analysis, an analysis of policy documents related to the COVID-19 pandemic was conducted. This process resulted in the identification and extraction of 208 policy target keywords. Subsequently, policy target keyword co-occurrence networks were constructed for each time period based on the relationships between the extracted policy targets in the documents, as shown in Figure 3, where each node represented a policy target, and edges between nodes represented co-occurrence in policy documents. The size of the nodes was determined by the frequency of occurrence of the policy target, and the thickness of the edges was determined by the frequency of co-occurrence of two policy targets.

To gain insight into the historical evolution of COVID-19 policies, eigenvector centrality was calculated for each node in the network, and the top ten policy target keywords with the highest eigenvector centrality were listed in Table 4. A comparative analysis of the core policy target keywords across different stages of China's response to the COVID-19 pandemic was conducted.
COVID-19 pandemic revealed several key findings:

(a) stage 1

(b) stage 2

(c) stage 3

(d) stage 4

Figure 3. China's COVID-19 Policy Targets Co-occurrence Network, stage 1-4.

(1) In stage 1, the central policy target was "COVID-19 prevention and control," which had the highest frequency and eigenvector centrality and was closely linked with "safety and health" and "implementation of the central strategy," which ranked among the top three in terms of eigenvector centrality and co-occurrence frequency. At the same time, the government also implemented measures to support the resumption of work and production, provide financial support, and ensure the orderly functioning of various industries. However, the market activation and support measures were primarily targeted towards the production of medical supplies and daily necessities, with the primary objective being to support the efforts to control the spread of the virus. In conclusion, the government prioritized efforts to combat the COVID-19 epidemic, placing it ahead of other market-related objectives.

(2) In stage 2, the core policy target remained "COVID-19 prevention and control." However, there was a shift in the combination of core policy targets, which included "economic and social development." This suggests that the government gradually shifted its focus to economic and social issues. Despite this, the government's priority still remained on epidemic prevention and control, with core targets related to this objective including "Precise and differentiated epidemic control strategies," "Personnel and materials supply," and "Medical treatment."

(3) In stage 3, there is a noticeable trend towards a more coordinated and unified approach in formulating macro-level policy targets. The difference in eigenvector centrality between the two core targets, "COVID-19 prevention and control" and "economic and social development," has reduced. This shift towards economic and social development is further emphasized by specific policy targets that focus on promoting economic development through various means, such as laws, foreign trade, and market environment. This highlights the paramount importance placed by the government on social and economic development.
(4) In stage 4, there is a heightened policy relevance, with a more discernible clustering and interconnectedness among policy targets, forming a systematic planning system that concurrently facilitates economic development and epidemic prevention and control. The core targets in this stage are almost consistent with those in the previous stage, such as "COVID-19 prevention and control" and "economic and social development", which highlights the Chinese government's commitment to integrating epidemic prevention and control with economic and social development. The policies emphasize the consolidation of prevention and control outcomes, such as "preventing the resurgence of the epidemic", "preventing the importation of the epidemic", "consolidating the outcomes of prevention and control", and "preventing the spread of the epidemic".

In summary, China's epidemic prevention and control policy targets have evolved from "emergency prevention and control", "prevention and control while stabilizing the economy", and "economic and social development", to "consolidating prevention and control results and promoting economic development". The sub-targets of epidemic prevention and control have evolved from treatment, material supply, and prevention of epidemic spread, to early detection and prevention, and to prevention of epidemic importation and resurgence. These targets are specific, up-to-date, and constantly optimized. However, there may be a paradox between pandemic prevention and control and economic and social development, as achieving both targets simultaneously may be challenging without effective vaccines and new measures to address COVID-19.

**Table 4. Top 10 China’s COVID-19 policy targets**

The **Evolution of Policy Tools**

The policy tool classification model was utilized to categorize the policy units, resulting in the identification of 8517 basic policy tools, spanning three categories and 14 second-categories. As depicted in Table 5, there is a noticeable disparity in the distribution of policy tools, with 68.8% classified as environmentally-oriented, 23.8% as supply-oriented, and 7.3% as demand-oriented. This suggests that the government primarily employs "top-down" measures to manage the spread of the epidemic, by creating a favorable policy environment and directly supplying resources and services, while disregarding the pull effect from the demand side.

Firstly, the utilization of supply-oriented tools is relatively limited. Among these policy tools, public enterprise constitutes the largest proportion (12.0%), followed by infrastructure development (6.2%), and talent cultivation (3.1%). This indicates that the government prioritizes strategies that directly support epidemic prevention and
control measures and provides impetus for epidemic prevention and control through human, material, and service support. However, fund support and technical support tools only account for 1.1% and 1.4% respectively, suggesting that more attention needs to be given to fund allocation and application of science and technology in policy formulation. Strengthening these areas through increased fund support and technical assistance is imperative.

Secondly, the government heavily relies on environment-oriented policy tools throughout the four stages. The most frequently used policy tools are legal regulation and target planning, accounting for 26.2% and 33.7% respectively. However, financial support, tax incentives, and political support are relatively minor in proportion. Therefore, the government should also consider issuing more varied policy tools related to financial support, tax incentives, and political support in detail, rather than solely relying on general legal regulation.

Lastly, the use of demand-oriented policy tools is insufficient across the four stages. This indicates that the Chinese government focuses primarily on boosting the epidemic response through increasing supply and creating a favorable policy environment, but overlooks the need to stimulate development from the demand side. Demonstration projects, service outsourcing, and government procurement policy tools all account for less than 2%, with government procurement policy tools only accounting for 0.1%. This suggests that the government needs to introduce more measures to attract social and market forces to participate in the epidemic response and economic development.

In conclusion, the COVID-19 policy tools employed in China exhibit a tendency towards emphasizing environmental creation over demand stimulation, relying on government intervention over market forces, prioritizing regulation over cooperation, and favoring coercion over guidance.

Table 5. Distribution of policy tools

CONCLUSION
This study aims to shed light on the content and dynamics of the policy texts issued and implemented in response to the COVID-19 pandemic by conducting a keyword co-occurrence network analysis of policy targets and identifying policy tools, which will provide valuable insights and lessons for future epidemic prevention & control efforts, not only in China but also in other developing countries.

To summarize, in terms of policy targets, the policy targets of the Chinese government during the COVID-19 pandemic have gone through several stages, reflecting the changing characteristics of the outbreak and the government's response. In stage 1, the focus was on COVID-19 prevention & control, with the government striving to ensure basic livelihoods and implementing emergency control measures to prevent the spread of the virus. In stage 2 and stage 3, the policy targets shifted to a combination of epidemic prevention and economic development, with the government adopting flexible and tiered measures to control the spread of the virus. In stage 4, the government tried to balance the targets of epidemic prevention and economic and social development, with a relatively greater emphasis on nucleic acid testing.

Throughout the response process, the government attached great importance to implementing central deployments and spiritual indicators, reflecting the political advantage of unified leadership in China. However, some shortcomings were also revealed, such as the shortage, uneven distribution, and inefficient use of emergency health resources, as personnel and materials supply has been one of the core policy tools and important tasks of the
epidemic response in the first two stages. China's large population and relatively scarce medical resources exacerbate the problem of uneven distribution of medical resources, with quality medical resources mainly concentrated in first- and second-tier cities. In addition, people's lack of understanding of the actual situation of the epidemic caused panic, leading to the hoarding of large amounts of health resources, which resulted in waste of health resources and forced the government to build more health resources than needed, causing waste of financial and human resources (Li et al., 2020a; Li et al., 2020b).

The policy target of nucleic acid testing only emerged in the fourth stage and was not included in the top ten central targets. Medical-related targets such as "personnel and materials supply" and "medical treatment" were the core policy targets throughout the pandemic, indicating that China's public health resources were mainly used for the medical treatment of the population. However, in preventive fields such as nucleic acid testing, resources were inadequate for the large population. Information disclosure related targets were not included in the core policy targets, and public health information disclosure was not timely enough, indicating a need to increase the scope and degree of information disclosure.

In terms of policy tools, China's response to the COVID-19 pandemic has primarily relied on environment-oriented policy tools, while supply-oriented policy tools have been relatively limited in their application, and demand-oriented policy tools have been severely lacking. These findings are consistent with the research conducted by of Ma et al (2020). Specifically, legal regulation and target planning tools have accounted for a significant proportion of the policy tools used, exceeding 50%, while the utilization of financial support, technical support, government procurement, service outsourcing, and demonstration project has been relatively low, accounting for less than 2%. This indicates that the government needs to optimize the application of environment-oriented and supply-oriented policy tools, with particular emphasis on leveraging market forces, social organizations, and public engagement to enhance diseases resistance. Of particular concern is the relatively weak level of financial support, with the government's related policies involving funds support in supply-oriented policy tools, financial support and tax preference in environment-oriented policy tools all exhibiting low levels of involvement. Among them, funds support accounted for only 1.1%, while financial support and tax preference accounted for only 3.4% and 2.6%, respectively. China's government health expenditures as a percentage of GDP have historically been very low, with less than 1% from 2000 to 2007 and reaching 2.16% for the first time in 2020. This proportion is not only lower than the average level of developed countries such as Germany, the United Kingdom, and Japan, but also fall short of the level of public health government investment in developing countries (Zhu et al., 2022). Overall, at the national level, the process of formulating public health policies before and after the outbreak of the pandemic has been characterized by a lack of financial investment and specific financial policies, which has made it challenging to promote the development of the medical system and garner joint response from the public and enterprises in addressing the to the pandemic.

IMPLICATION
The analysis of previous epidemic prevention & control policies in China underscores the need for further improvements in several key areas. Firstly, there is a need to develop remote medical technology and improve the tiered diagnosis and treatment system to achieve rapid and equitable distribution of medical resources. Secondly, greater attention should be given to timely detection and prevention of epidemics, and a public health awareness of "prevention is better than treatment" should be established. Thirdly, information disclosure should be strengthened to facilitate effective epidemic monitoring and response. Fourthly, multi-party participation should be strengthened in epidemic prevention & control efforts. Fifthly, greater financial investment in medical care is necessary to support effective epidemic prevention & control measures. Finally, policy tools and targets should be coordinated to improve policy effectiveness.

ABSTRACT
An explosion at the Port of Beirut resulted in over 200 fatalities and displaced many more. Hundreds recorded and thousands shared the event, sparking discourse across social media. We provide a mixed-methods analysis of 26 TikTok videos about the port explosion. Our study involved a semiotic analysis of the videos and a content analysis of the related 21,150 comments. The discourse surrounding the explosion extends a growing body of literature on the role of TikTok in disseminating crisis-related information. We use a collective sensemaking framework to investigate how TikTok contributes to the understanding of an event. The authors find that Middle Eastern content creators contributed more to collective sensemaking about the event than non-Middle Eastern creators. We additionally examine the current state of collective sensemaking on TikTok and provide platform implications.

INTRODUCTION
On August 4th, 2020, the Port of Beirut in Lebanon exploded due to the detonation of misgoverned ammonium nitrate that had been stored in one of the port’s warehouses since October 2014 (Ballout, 2023). As a result, there were over 200 fatalities, thousands displaced, and significant damage to the city’s infrastructure. The explosion occurred during an already vulnerable time for Lebanon as the country was facing consequences of political corruption and instability, COVID-19, and a worsening economic crisis. There have been ongoing investigations of what exactly caused the explosion, as rumors, speculations, and conspiracy theories spread. As of April 2023, justice has not been served for those impacted by the explosion. This includes those who lost their lives, and the Lebanese communities that have not seen a beneficial change in government leadership.

Initially, a fire in the port alerted emergency responders as Beirut citizens started recording the resulting smoke cloud (see Figure 1). Those already recording captured the second, larger explosion that caused the fatalities and infrastructural damage. Lebanese diaspora worldwide were glued to their phones after the crisis, as those on the ground and citizen reporters kept the world up-to-date. Information was communicated via multiple social media channels, including TikTok. Hundreds of uploaded TikTok videos, with hashtags like #lebanonblast or #prayforlebanon, were viewed over 100 million times. TikTok helped enable a local crisis event to be discussed amongst a global audience, with video creators from around the world. Some influencers took it upon themselves to share about the explosion, initiating discourse about the international disaster with their thousands or millions of followers. Plentiful research has examined the use of social media for collective sensemaking during a crisis event, mainly with a focus on the Twitter platform (e.g. Dailey & Starbird, 2015; Fischer-Preßler et al., 2019; Heverin & Zach, 2012). However, few studies have focused on the TikTok platform.

We address this gap using sensemaking theory and analyzing 26 TikTok videos and their corresponding 21,150 comments. Dervin’s theory of sensemaking focuses on how individual behaviors can contribute to the collective sensemaking of others (Dervin, 1998). Rooted in this sensemaking theory, our study explores and examines the collective sensemaking process of the Port of Beirut explosion. TikTok’s multimodal content including visual, auditory, and textual elements encouraged a mixed-methods approach including semiotic analysis and content analysis. We find that the volume and timing of the discourse around the disaster resembles a viral event, or a viral topic (Nahon & Hemsley, 2013). We analyze the difference in comment behaviors for videos created by Middle Eastern content creators, influencers, and for videos that include a TikTok sound. Lastly, we discuss platform implications pertaining to collective sensemaking and potential future research endeavors.

BACKGROUND: TIKTOK AND COLLECTIVE SENSEMAKING
TikTok
TikTok, a Chinese social media application founded in September 2016, had an initial focus on entertainment content, such as lip-syncing or dancing videos (Montag et al., 2021). Over time, TikTok has grown to have an estimated 1 billion global users that produce and share videos about healthcare, fitness, life hacks, and more (Ruby, 2023). Being in the contemporary media landscape, TikTok features multimodal content that permits audio, visuals,
and other means to deliver a message. Although multimodal communication is available via other platforms, TikTok’s sociotechnical structure shifts the engagement pattern from friend-focused to content-focused (Zulli & Zulli, 2022). This provokes research that examines TikTok’s function in engaging crisis content. Each user’s For You Page (FYP) is curated with custom content suggested by the platform’s algorithm. Users can like, comment, save, repost, duet, or send the video to friends in and outside of the application. Comments can be liked, disliked, and replied to; if the creator of the video conducts any of these actions, it is visually emphasized with a “Liked by creator” tag or by focusing on the creator’s comment via collapsing other replies. Inter-application messaging is available in the Inbox, which also alerts users to their friend’s activities or available ‘live’ videos from creators they follow. However, a majority of user activity resides in their FYP.

The emergence of TikTok scholarship is recent, leading to a comparatively small volume of available literature. However, significant strides have already been made as multidisciplinary researchers consider TikTok’s societal and cultural impact on subjects from healthcare to algorithmic othering. Some examples include Bhandari et al.’s highlight of ‘the algorithmized self’ which constitutes self-representation on the application (2022) and Zulli et al.’s research on imitation publics on TikTok. Demographically, approximately 50% of TikTok users are below the age of 24 years old (Iqbal, 2023) aligning with the generation more likely to use social media for activist pursuits (Tyson et al., 2021). From the years of 2019 to 2022, TikTok’s annual users grew by over 380% to more than 1 billion users globally (Iqbal, 2023). Although there is concern about the application’s potential ban due to political tensions between the United States and China, a prominent community is still engaging in online information behaviors that are worth examining. Indeed, Dervin (1998) argues that individual information behaviors can contribute to collective sensemaking, thus we examine this particular phenomenon on TikTok.

**Collective Sensemaking**

Sensemaking focuses on information seeking and use to construct one’s own understanding of the world. Dervin describes sensemaking as a dynamic process of new information situations that an individual emotionally, cognitively, or physically negotiates with (Dervin, 1998; Naumer et al., 2008). This process is incremental through the transformation and integration of new information into cognitive schemata, which is essential in crises as sparse information is used for decision-making (Pentina & Tarafdar, 2014). Social media provides a platform for human-mediated information processing and exchange, where individuals collectively undergo the sensemaking process for a given subject. Previous collective sensemaking scholarship has focused predominantly on Twitter. (Reuter & Kaufhold, 2018). However, there exists a small body of literature considering sensemaking on TikTok (e.g., Schellewald, 2022). There is a need to examine the process of sensemaking at the digital locations used for crisis communication. This is where the TikTok platform comes into play, acting as our research field site.

**RESEARCH QUESTIONS**

**RQ1:** How does the use of TikTok contribute to collective sensemaking during a crisis?

**RQ2:** How does the nature of collective sensemaking on TikTok change over the course of a crisis?

**METHODOLOGY**

**Data Collection**

To examine the discourse pertaining to the August 4, 2020, Port of Beirut explosion, snowball searching was used to discover relevant hashtags. The process began by searching for hashtags related to #lebanonblast. We only considered hashtags with more than 5,000 views, and for each hashtag, only the top videos with more than 10,000 views were included. This was done to filter out videos that used the hashtag incorrectly, like bot videos, and to focus on videos that spanned a larger reach. After collecting the videos from each hashtag that met the criteria, accompanying hashtags from the resulting videos were used. An example is provided in Figure 1, which is a video that includes the hashtag #lebanonblast and relevant hashtags #prayforlebanon and #التفجير_بيروت (beirut_explosion in Arabic). We used ScrapeTikTokComments.js - a publicly available web scraping script - to collect information for 26 videos. The following data were collected: URL, Creator Name, Creator Number of Followers, Video Posted Date, Number of Likes, Number of Comments, and Comments. A limitation of this work is that the tool only collects up to the top 3,000 comments per video. A total of 21,150 comments were collected. Additionally, we recognize the ethical dilemma of collecting social media data; to mitigate, we emphasize anonymity of creators and point to the research goal of highlighting the significance of typically marginalized communities experiencing crisis.

**Data Analysis**

The analysis was divided into two main components: videos and comments. We analyzed videos with a semiotic analysis approach, and comments with content analysis, classification modeling via Bidirectional Encoder Representations from Transformers (BERT) (Devlin et al., 2019), and time series analysis of collective sensemaking.
I. Videos
Gillian Rose’s “Visual Methodologies” (2016) informed our video analysis, with a specific focus on semiology, the study of signs, which questions how images make meanings. The semiotic analysis looked at how each individual video collectively contributed to a cultural understanding of the crisis event. Given the varying lengths of the TikTok videos, we analyzed the auditory, visual, and textual signs at the following time increments: cover page, ½ through, ¾ through, and last section. For example, a 45-second video’s signs would have been analyzed on its cover page, at 15 seconds, 30 seconds, and then at the end.

Additionally, videos were tagged with three of the following attributes:

- Originating from a Middle Eastern content creator
- Creator having more or less than 500,000 followers, as a way to signal influence
- Using a TikTok sound or music, or using the original audio of the video

II. Comments
The characteristics of our population of TikTok comments include:

- Short comment length, with an average of 38.2 characters per comment. Although the maximum length of a comment is 150 characters, TikTok users in this comment set had on average much shorter comments.
- Frequent use of emojis, with approximately 31% of comments containing emojis.
- Multiple languages, with at least 10 languages detected in comment exchanges.
- Comments being highly relevant to the content of relative video, but not always so.

To preserve the sentiment of emojis, the UNICODE_EMOJI dictionary in the Python emot.emo_unicode module was used to convert emojis to text representations. Additionally, as there were multilingual comments, the GoogleTranslator class from the deep_translator package was used to translate comments into English. We note that there are contextual and cultural limitations that come with using a standard translation tool.

Content Analysis
While our approach to annotating comments falls within a methodology of quantitative “content analysis” (Krippendorff, 1980), technically the content is “discourse” focused. Comments are often responses to the video or ongoing discussions in the comments. While the comments are annotated in isolation, a large portion of what the machine learning methodology captures is a classification of the pragmatic function of a comment in an ongoing discourse. In early comparisons, we found a remarkable similarity to the codebook provided in Heverin and Zach’s (2012) collective sensemaking study. This enables a comparison of the content related to the Lebanese crisis to theirs.

In Heverin and Zach’s study, tweets were analyzed for collective sensemaking of three college campus shootings in the United States (2012). Given the relevancy of the article to our research, collective sensemaking themes from their study were used as the starting point for our codebook. After an initial inductive pass through the TikTok comments, the codebook was adjusted to reflect the international context of the field site and functionality of the TikTok platform. The tags, in Table 1 below, include both some of the original themes seen in Heverin and Zach’s study (Source: H&Z) and additional themes added by this study’s authors (Source: Original). As seen in *italics* below, some of Heverin and Zach’s codes were modified to fit the context of the study.
### Categories of Sensemaking Themes

<table>
<thead>
<tr>
<th>Source</th>
<th>Theme</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>H&amp;Z</td>
<td>Information Sharing</td>
<td>Individuals posting comments containing information. Individuals contributing to the collective conversation about the crisis.</td>

<td>Information Negotiation</td>
<td>Individuals questioning information contributed via auditory, visual, and/or textual signal in TikTok video.</td>
</tr>
<tr>
<td>H&amp;Z</td>
<td>Information Seeking</td>
<td>Individuals posting questions to the collective conversation about the crisis.</td>
</tr>
<tr>
<td>H&amp;Z</td>
<td>Talking Cure</td>
<td>Individuals communicating inner feelings, prayers, or thoughts without the expectation of receiving a response from others.</td>
</tr>
<tr>
<td>Original</td>
<td>Information Appreciation</td>
<td>Individuals sharing messages of appreciation for creators who spread awareness about the crisis.</td>
</tr>
<tr>
<td>H&amp;Z</td>
<td>Other</td>
<td>Comments that do not fit one of the other categories.</td>
</tr>
</tbody>
</table>

Table 1. Categories of Sensemaking Themes

Heverin and Zach’s codebook includes other collective sensemaking themes that were not included in our study’s codebook due to data fit and model fine-tuning. For example, one theme was “Understanding the Why” which is linguistically very similar to the “Information Seeking”. For the sake of linguistic clarity, these codes were collapsed. However, general findings about the use of comments for collective sensemaking are similar.

**Classification Model Analysis**

We used the BERT to classify our 21,150 comments into the six classes listed in Table 1. For simplicity, the authors decided to classify a comment in a mutually exclusive fashion, where a comment could be labeled with only one collective sensemaking tag. We randomly selected 1,936 comments from the dataset and manually labeled them via content analysis to create a training set for the BERT model. We fine-tuned the pre-trained BERT model on the training set and used it to classify the remaining 19,214 comments. The BERT model was selected for two main reasons. Firstly, BERT is a contextual language model that can capture the meaning of words in context, making it better suited for text classification tasks than the bag-of-words approach. Secondly, BERT is a pre-trained model that has learned the underlying structure of language from a large amount of text data, allowing it to extract relevant features for our classification task. These features can be fine-tuned on our specific task, resulting in better classification performance than training a model from scratch.

**FINDINGS**

**Result of the Classification Model**

We assessed our BERT-based classification model using key evaluation metrics, particularly focusing on the F1 macro score. The F1 macro score calculates the average F1 score for each class, ensuring that minority classes are not overlooked in imbalanced datasets. This comprehensive evaluation allows for a robust analysis of the classification results. Our model achieved a Macro F1 score of 80.88, with all classes exhibiting F1 scores above 80, except for the ‘Other’ class. This is due to the linguistic diversity of this class. Notably, the model demonstrated exceptional performance in the ‘Information Appreciation’ class, with a score surpassing 90.

Table 2. Results of BERT Classification Model
Description of Comment Tags
The following subsections primarily respond to our first research question, RQ 1, which is regarding the way in which TikTok facilitated sensemaking in crisis. Examples of each comment are paraphrased to prioritize anonymity of the users; however, each paraphrase remains similar to the original comment to preserve sentiment.

Information Sharing
Information Sharing comment examples include “we are corrupted, not at war”, “Donate to Red Cross – they are not corrupted”, “commenting for the algorithm.”, and “explosion not fireworks, they are not made from ammonium nitrate...”

Information sharing had the highest frequency of collective sensemaking tags, given the popular behavior of exchanging information generally pertaining to the crisis. Comments of this type contribute to collective sensemaking as individuals posted information about the crisis or replied to inquiries posted by other users. Similar to Heverin and Zach’s Information Sharing tweets, these comments helped fill the cognitive gap to build a collective picture of what occurred. There were five main types of Information Sharing comments. ‘Background Information’ included individuals adding cultural, political, or economic information to help set the social context of the crisis. ‘Crisis Help’ included individuals providing information about seeking safety or safety precautions. Similar to Crisis Help, ‘Crisis Response Actions’ included individuals discussing appropriate crisis response steps or recipients of donations. ‘Conscious Comments’ included individuals commenting with the clear intention of trying to “boost” the algorithm. Lastly, ‘Tagging’ includes individuals tagging (@-ing) accounts – both with a low and high follower count – to share the video with them.

Information Negotiation
Information Negotiation comment examples include: “Why did you choose this song?” and “Why the world peace hashtag, it was a leak...”

In Heverin and Zach’s research, Information Negotiation comments reflected the more contentious nature of discourse as users questioned contributed information, asked for clarification, or stated they had the correct information (2012). We adjusted Heverin and Zach’s definition of “Information Negotiation” to reflect the multimodality of information on TikTok. It is in this category of collective sensemaking comments that we see the flexibility of information mediums, as users interpreted information not only from comments but also from the semiotic elements of the video. The strength of pairing content analysis with semiotic analysis is the ability to connect the several sources of information that come with multimodal content. Intersemiotic dissonance is when elements diverge semiotically rather than merge to inform a unified meaning (Yu, 2021). A majority of information negotiation comments represent the intersemiotic dissonance that motivates users to comment with disagreement on an element of the TikTok video, including a hashtag, selected sound, or textual element. These comments can create noise, impacting the efficacy of information exchange relevant to the crisis (Khoury, 2023). Thus, information negotiation comments do not contribute to collective sensemaking.

Information Seeking
Information Seeking comment examples include: “Why did it blow up?” and “Is your family and you ok? 🙏💔”. Comments of type Information Seeking are more straightforward in nature. Typically using who, what, where, why, and how language, individuals seek information to help fill cognitive gaps. Information seeking comments thus contribute to collective sensemaking.

Talking Cure
Talking Cure comment examples include: “Praying for Lebanon from Cambodia 🇱🇧” and “astaghfirullah ya Allah….save me always... #prayforlebanon”.

Crisis communication can also include discourse that comes from the personal, cathartic perspective of the individual. Individuals posting comments about their overall sentiment towards the event are not necessarily providing a response, but instead care about expressing prayers, thoughts, or an otherwise emotional utterance. Popular across crisis communication are individuals stating their “thoughts and prayers” are with the impacted community, which can spark debate amongst those who demand mobilization. In general, Talking Cure comments do not greatly contribute to collective sensemaking. However, given the importance of religion in Lebanon and the greater Middle East, these comments still are included in the collective sensemaking collection as the global world can observe about talking cure culturally differs. Included in Talking Cure comments is the discourse of type ‘Commemorative Information’. ‘Commemorative Information’ included individuals paying their respects to those passed, injured, displaced, or somehow else harmed.
Information Appreciation

Information Appreciation comment examples include: “As a Lebanese, thanks for using your platform to help share.” and “Yes! Someone spreading awareness about Lebanon on TikTok!!! 😊”

A code added into Heverin and Zach’s original codebook is ‘Information Appreciation’, as individuals commented messages of appreciation to those sharing videos about the explosion. Many of these individuals were Lebanese, demonstrated either by their self-identification in the comment or by inferring the motivation behind their comment. The greater Middle Eastern community is aware of how the world can normalize crisis events in the Middle East, or how mainstream media outlets pay little to no attention to what is beyond the Global North. Thus, when TikTok users from the Lebanese community saw accounts - especially those with a large amount of followers - share information about the crisis, they commented their appreciation. These comments can contribute to collective sensemaking indirectly as the broader community becomes aware of the sentiment of the impacted country. As individuals post their appreciation comments that hint towards the marginalization of previous crises, they signal their know-how. Other users are able to reply with talking cure, information seeking, or other categories of comments.

Other

Other comment examples include: "you shouldn’t joke about this...", and "Who is from Bulgaria?"

Lastly in the codebook are comments that did not fit any previously stated comment category. Intuitively, comments in this category are widespread contextually and linguistically. There are three main types of these comments. ‘Joke’ comments include sharing nonserious/humorous commentary about the crisis event. Although there is previous literature about the use of humor in crisis communication, this was not a code relevant to the scope of our study. ‘Anti-Joke’ comments included individuals ridiculing creators of ‘Joke’ comments. ‘Spam’ comments included individuals commenting content that did not pertain to collective sensemaking or otherwise were undecipherable. Generally, comments in the ‘Other’ category do not contribute to collective sensemaking.

Discourse Over Time (Overall, First Month, First Week)

The following subsections primarily respond to our second research question, RQ 2, which examines the nature of collective sensemaking over the course of a crisis. We used time series analysis to look at the trend of the collective sensemaking tags over the span of three years (2020-2023), one month after the explosion, and one week after.

Information Sharing, Talking Cure, and Other comments were the most common comments in contrast to Information Negotiation, Information Seeking, and Information Appreciation comments. Approximately 60% of the comments occurred within the first month of the explosion, and 51% of the comments occurred within the first week of the explosion. The rate of growth and decay of the discourse comments over time resembles a viral event or what Nahon and Hemsley call a viral topic (2013). Viral topics emerge out of many viral events and often reflect what a society deems as important at a given time. In viral events, network gatekeepers are key proponents of information diffusion – or movement of information - as they broadcast content into their own networks, based on their own curation logics (Thorson & Wells, 2016). In the case of the Port of Beirut explosion, there are a few reasons why a TikTok user would have come across content related to the disaster. TikTok creators, acting as gatekeepers, who paid close attention to the explosion generated information and passed it into their followers’ networks. Additionally, the FYP functioned as an algorithmic gatekeeper as it recommended content to its users based on the content the users browsed (Bhandari & Bimo, 2022).

Figure 2 shows two peaks about the viral topic of the Port of Beirut explosion from 2020 to 2023. The first one happened in 2020, right after the event happened, and the other smaller one was in 2022, indicating that people reshared information about the explosion, which resulted in the formation of the smaller peak (Nahon & Hemsley, 2013). The spikes in 2022 were due to videos sharing “new angles” of the blast and clips of a new Lebanese short created to commemorate the experiences of those impacted. Therefore, spikes in comments can be broadly attributed to commemoration that re-stimulated discourse.
Figures 2-4: Trends of Sensemaking Tags Over Time, First Month & First Week

Figures 3 and 4 show the trend of the six sensemaking tags one month and one week after the explosion respectively. We zoom into the one-month and one-week period to explore what information users were sharing right after the explosion event in contrast to the 3-year span. Both figures show similar viral trends like Figure 2, but there are nuanced differences. For example, both Figures 3 and 4 show that users shared most of the information on August 5 and 6, 2020, the 2 days after the explosion, which formed the peak that is shown across the three graphs. However, Information Sharing had the highest frequency in Figure 2 in 2020, while Figures 3 and 4 show that ‘Other’ comments were the most used discourse type for approximately the first 2 days until Information Sharing and Talking Cure comments took lead. This trend aligns with the paradoxical role media plays in being both a source of relevant information and information overload, leading to suboptimal information processing (Pentina & Tarafdar, 2014).

Significance of Middle Eastern Creators, Influencers, and TikTok Sounds

To further examine gatekeepers, each video’s creator was tagged for being a Middle Eastern (ME) content creator, having more than 500,000 followers, and for choosing to incorporate a TikTok sound. By formulating three hypotheses around these three attributes, we explored how video creators and their decisions influence comment behavior.

<table>
<thead>
<tr>
<th>Middle Eastern Content Creator?</th>
<th>More than 500K Followers?</th>
<th>Uses TikTok Sound?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>9</td>
<td>12</td>
</tr>
<tr>
<td>No</td>
<td>17</td>
<td>14</td>
</tr>
</tbody>
</table>

Table 3. Frequency of Videos Per Attribute

$H_0$: There is independence between the background of the content creator and the behaviors of comments.

$H_0$: There is independence between influence, determined by follower count, and the behaviors of comments.

$H_0$: There is independence between using a TikTok sound and the behaviors of comments.

A chi-square test is used to test these hypotheses as it can determine if a connection between categorical variables exists (Singhal & Rana, 2015). For each chi-square result, the p-value of <0.001 indicates we can reject the null hypothesis, that there is independence between each attribute and commenting behavior. Examining Figure 5A reveals that there is not a significant difference in Information Appreciation and Information Negotiation comment behavior between videos created by ME and non-ME publishers. While non-ME creators made more videos, ME creator videos had nearly double the amount of the rest of the comment types. As Information Sharing and Information Seeking comments more directly contribute to collective sensemaking, we see that ME creators sharing about the Port of Beirut explosion contributed more to collective sensemaking than non-ME creators. This may be due to their ethnic background signaling more credibility in discussing the subject matter, their follower’s increased interest in the topic, or another factor.

Figure 5B reveals that creators with more than 500,000 followers, or influencers, tend to receive more Information Appreciation comments. Their followers, cognizant of the creator’s influential status, see the role the video plays in information spread. However, videos made by creators with less than 500,000 followers tend to have more of every other comment type. Figure 5C illustrates TikTok videos using a selected sound having more Information Negotiation comments than videos using the original audio, indicating intersemiotic dissonance. As the selected sound was just one semiotic signal type, further research is needed to understand the relationship between specific semiotic decisions creators make and the impact on the collective sensemaking of an event.
We note the importance of considering the TikTok creators, regardless of ethnic background or follower count, in the sensemaking process. In sensemaking, a single individual cannot have a complete understanding of reality. Instead, we are dependent on multiple perspectives to make sense of information-sparse events. Conducting a semiotic analysis of the videos revealed numerous vantage points and footage that, together, helped form an understanding of the crisis event.

**DISCUSSION AND NEXT STEPS**

**Richness of Collective Sensemaking**

Outlets like TikTok can help combat the marginalization of international events by Western media. Both Lebanese and non-Lebanese chose to engage with information about the event. Although we cannot necessarily point to the motivations of the creators of the videos, we can say that information diffusion was an important part of this engagement. This was seen with influencers spreading awareness about crisis relief efforts and with citizens of Beirut sharing the horrors of their destructed city. The sensemaking discourse that occurred on the application was mostly surface-level. The algorithm's temporal element follows and enforces virality, as TikTok prioritized videos in the FYP during the “peak” time after the disaster event. As of April 2023, approximately 2.5 years after the disaster, the Lebanese community is actively discoursing and investigating the circumstances and offenders of the explosion. Lebanese are steadily broadening their cultural understanding of the circumstances that led up to the event, and the global community has already shifted its attention elsewhere. This situation is not unique, as communities worldwide seek attention from the global community for recognition and awareness of their country’s dilemmas. As a platform, TikTok has the power and potential to alter how cultural events are understood. Using a design or human-computer interaction theoretical lens, the platform can be inspected for how to more richly fill cognitive gaps of crisis events typically marginalized by the global community.

**Mis(information) Sharing**

In addition to the richness of collective sensemaking is the accuracy of information used to fill cognitive gaps. While information sharing comments most directly contribute to the collective sensemaking of a crisis event, they also additionally represent venues of misinformation. Qualitatively looking through the comments revealed inaccurate comments claiming the explosion to be a part of the Ukrainian invasion, or causing thousands instead of hundreds of fatalities. Although TikTok users are capable of correcting false information by replying to inaccurate comments, these replies are by default collapsed and thus not viewable at first glance. The exception is if corrective comments are made by creators commenting on their own videos, as TikTok visually prioritizes their comments. However, the labor of correction cannot be solely dependent on human interaction. We saw the platform warnings of inaccurate information at the video-level when creators uploaded information regarding COVID-19. An examination is required to consider how TikTok can help combat misinformation at the comment-level.

**Examining ‘Other’ Comments**

It should be noted that the model performance of our ‘Other’ category was worse than the others. This was expected as there were many different kinds of messages in this category that were hard for BERT to categorize. A significant amount of these were humor oriented, which is a difficult category to capture with independent codes (Boxman-Shabbat & Shifman, 2014). Previous research has already examined the role humor plays in crisis communication (e.g., Kuipers, 2002). Although jokes and their critical ‘anti-joke’ replies were observed in the dataset, their frequency was not sufficient for classification. Additionally, the added complexity of multi-lingual humor being captured made sarcasm and humor detection difficult.

Creators who typically were not in the interest network of Lebanese/Greater Middle Eastern content and chose to share content about the disaster were generally met with gratitude, as seen in “Information Appreciation” comments. However, there was a double-edged sword as individuals from communities also facing some level of crisis criticized their selectivity. For example, comments like “What about the war in Syria?” or “Why are you not talking about the Uyghurs in China?” illustrate spurts of condemnation toward the creator. These “crisis comparison” comments were not pertinent enough to be classified individually and thus were included in “Other” comments.
Further research is needed to understand the role of both crisis comparison and joke/anti-joke comments in the collective sensemaking process of a crisis event.

CONCLUSION
This study contributes to the larger literature surrounding collective sensemaking by considering TikTok’s role in disseminating information about a non-Western crisis event. Using a mixed-method approach, we provide extensive discussion about the way in which crisis discourse functions on TikTok and the way audiences make sense of these crises. While our primary empirical work reported here is a quantitative content analysis, the discussion made heavy use of multimodal discourse on TikTok, considering visual data, audio, as well as text. In the future, we will develop a more systematic approach to studying the semiotic phenomena occurring between commentary and the videos themselves. We recognize the heaviess the explosion still has on the Lebanese people, and the dire economic and political situation the country is currently battling. To remember the lives lost as a result of the explosion, the martyrs are listed here: https://tinyurl.com/beirutmartyrs.

Examining Social Media Policy and Records Management in Massachusetts Municipal Governments

Kriesberg, Adam  Simmons University, USA | adam.kriesberg@simmons.edu

ABSTRACT
This paper reports on an exploratory analysis of the social media policies of municipal governments in the Commonwealth of Massachusetts. With a strong Public Records law and language clearly indicating that social media posts are government records, Massachusetts provides a framing for research into municipal policy on social media use, retention, preservation, and access. Of the 351 municipalities in the Commonwealth, just 87 have publicly accessible Social Media policies. These policies indicate that municipal governments take their responsibilities around social media records management seriously, they do not offer many specifics around how they will engage directly with posts from privately-owned social media platforms. Implications of these findings suggest that the digital preservation community must continue to develop tools and methods to preserve social media records the support broader efforts around government transparency and accountability, as well as advocate for platforms to include features to support responsible public sector social media use.

KEYWORDS
Government records management, information policy, social media policy, digital preservation, social media archiving

INTRODUCTION
Governments have long faced challenges in information management brought about by changes in recordkeeping technology. Over the course of the 20th century and into the 21st, these challenges have primarily focused on the opportunities and affordances of the internet, and the new ways public sector institutions create, manage, disseminate, and preserve information for various constituencies. Governments at all levels and around the world have taken advantage of the emergence of social media platforms such as Facebook, Twitter, and Instagram to connect directly with constituents. The affordances of these platforms have made their use particularly valuable at the local level, where governments and public sector entities such as local fire departments, school systems, or offices of Public Works can get their message out directly to local constituencies that follow municipal accounts.

Much of the current research on social media preservation has focused on efforts undertaken by researchers and the US Federal Government. This paper extends the scope of these efforts by analyzing a group of government Social Media policies at the municipal level in Massachusetts and considering the records management and preservation implications of current social media management practice. The results of this study suggest that many city and town governments do not provide details on how they manage and retain social media records, nor do they maintain a social media policy articulating their use and terms of engagement with these platforms.

This paper is motivated by the following research questions:

- How do local governments manage and preserve social media records?
- What topics do social media policies for municipal governments in Massachusetts address, and what do they omit?
- How does state records management law affect records policy at the local level?

The remainder of this paper proceeds in five sections, beginning with a literature review examining social media use, management, and preservation in the public sector. Following an explanation of the methods used in this study are the results of an analysis of 351 municipal websites for cities and towns in Massachusetts. The discussion section considers the implications of these results, and a final conclusion suggests potential avenues for additional work to advance this avenue of research.

LITERATURE REVIEW
Social media platforms are used widely across many parts of contemporary society, including by governments around the world who take advantage of the affordances of these software environments to connect directly with citizens. The ways in which politicians and other government actors use social media has been the subject of numerous research studies (e.g. Kalsnes et al., 2017; Kavanaugh et al., 2012; McCammon, 2020; Netshakhuma, 2019), although preserving materials from these platforms has proven to be difficult (e.g. Breuer et al., 2020; Thomson & Kilbride, 2015). As dynamic digital environments resulting the creation of vast amounts of user-generated content as well as trace data, social media platforms continue to be of interest to scholars and other...
Archivists and digital preservation professionals have articulated the existential challenges of managing electronic records for decades. Margaret Hedstrom named electronic records as “one of the greatest challenges facing the profession” in 1991, as even then these materials were entrenched in many areas of society including (notably for this study) across the public sector (Hedstrom, 1991). Yet many of the issues raised in this article persist today. Social media records exemplify the current state of digital preservation challenges, as they are created on privately controlled platforms and hard to interpret outside of these contexts. Furthermore, they are not discrete records but rather living digital objects that can be simultaneously engaged with over time by platform users while being subject to records management laws and policies.

More recent research from the digital preservation and records management communities have pointed out some of the drawbacks of current records management practice in organizations. Duranti (2010) highlighted the inherent problems with a strategy employed by many organizations that “print and file” digital records or scan paper documents for retention in a repository. These approaches often result from a lack of clear, consistent policy and standards around digital records management. The “print and file” philosophy for electronic records management was widely utilized by the National Archives and Records Administration (NARA) from the 1980s through the 2000s, as electronic records became the single largest set of records produced by the federal government (Johnston et al., 2019). This has now largely been abandoned in favor of the capstone approach, which seeks to apply archival concepts of appraisal to target the collection of only those individuals in an agency who’s emails are understood to be more representative of the organization as a whole (Noonan, 2016).

Subsequent work from the records management community has explored other ways in which digital environments force information professionals to question some assumptions about how to manage electronic records (e.g. Kallberg, 2013; Lemieux, 2016; Seymour, 2017). The importance of public sector records management is reinforced by the idea that these materials have significant value and represent a unique opportunity for governments to ensure transparency and accountability in government (Shepherd, 2006).

Clifford Lynch issued a call to action for digital curation professionals around the unique challenges of managing digital records from algorithmically-driven social media platforms (Lynch, 2017). The role of APIs in extracting and preserving social media data is complex and forces the community to confront what custody of digital records means in a digital environment where “the record” remains on platform even though it is curated and described in a repository (Acker & Kriesberg, 2019). A series of business and policy decisions at Twitter have altered the ability for some academic researchers to use Twitter as a source of data for research (Ledford, 2023). Changes such as these would certainly have an impact on preservation efforts as well, should repositories be unable or unwilling to pay for API access.

The increasingly widespread use of social media records for research across disciplines has in turn led to more focus being paid to social media records by digital preservation practitioners. A number of prominent social media archiving projects have launched in recent years, beginning with the lauded but unsuccessful Twitter archive at the Library of Congress (Bruns & Weller, 2016; Fondren & Menard McCune, 2018; Zimmer, 2015). The social science repository Inter-University Center for Political and Social Research (ICPSR) has launched the “Social Media Data @ ICPSR) project, known as SOMAR, which seeks to preserve social media datasets used in academic research contexts (Hemphill et al., 2021, 2018). Other projects based in academic libraries, such as SocialFeedManager, have made innovative use of APIs to extract and preserve social media data (Littman et al., 2018; Social Feed Manager, 2018). Finally, the Documenting the Now project has been working on issues related to social media curation and preservation since it was launched in 2016. The project maintains a repository of curated Twitter datasets (Documenting the Now, 2017; Galarza, 2018; Kalt & Scott, 2020).

Techniques to archive and preserve social media content continue to spread throughout the digital curation community. While some advocate treating social media sites like other web pages and using web archiving tools (e.g. Anderson, 2020), others have examined the potential of social media data archiving software such as ArchiveSocial, Pagefreezer, and Smarsh (Borji et al., 2022). Borji and colleagues compared these three popular commercial tools that preserve social media and found that while each offer a range of features for archiving these dynamic records including automatically archiving posts, scheduling and keeping deleted records, and the provision of digital signatures (Borji et al., 2022). Without ongoing, direct comparison between these tools, the differences in their products will remain difficult to ascertain.

While formal efforts to curate and manage social media data continue to develop, governments have faced immediate needs stemming from records created on social media platforms for years. The end of the Obama
Administration saw the first time social media records were collected by the NARA with limited engagement data and incomplete documentation available for future users of the materials (Acker & Kriesberg, 2017). Following the departure of Donald Trump from office and the ban he received on Twitter, various archival efforts worked to collect and preserve tweets from his @realDonaldTrump account (Kriesberg & Acker, 2022). As members of Congress worked to track down these tweets among other Presidential records, the Archivist of the United States acknowledged that while NARA had collected some data from Twitter it could not ensure the completeness of its holdings (Ferriero, 2022). Amidst these conversations, the company ArchiveSocial has contracted with NARA to manage preservation and transfer of social media records of both the Obama and Trump administrations (Ingros, 2021). These examples illustrate the hurdles faced by US federal agencies seeking to preserve social media data and ensure its ongoing availability. At more local levels of government, such as those described in this paper, limited resources make this work that much more challenging for town clerks, records managers, and municipal archivists.

This paper contributes to the growing body of research on managing and preserving social media records, adding a focus on municipal governments as institutions which are legal obligated to keep track of records created on social platforms. While these organizations may not have the robust archives and digital preservation infrastructure of university repositories or federal agencies, they have clear mandates to directly engage with the challenges inherent in social media preservation. As illustrated in the next section, the Public Records Law and related policy in Massachusetts make it well-suited for a statewide analysis of social media management policy.

**Public Records Law in Massachusetts**

The legal definition of public records varies widely around the world and across levels of government. Within the United States, some states have been explicit in describing different media and commenting on their status within the existing records framework. In Massachusetts specifically, municipal records are regulated under the jurisdiction of the state’s Public Records Law and Municipal Records Retention Schedule. Current law defines a “public record” as “All books, papers, maps, photographs, recorded tapes, financial statements, statistical tabulations, or other documentary materials or data, regardless of physical form or characteristics, made or received by a governmental entity” (Galvin, 2022, p. 45). While additional language in the law reduces some expectations for towns with populations under 20,000 people, based on this definition government social media posts should be understood as public records and subject to relevant regulations related to retention and preservation.

In addition, the state’s Executive Office of Technology Services and Security maintains a “Social Media Legal Guidance Toolkit” containing specific guidance on municipal social media use. This document is full of interesting and meaningful steps municipalities can take to protect, preserve, and provide access to their social media information. Municipalities and other government entities are advised to create and/or update policies related to social media use. These can include Privacy Policies, Terms of Use for government websites, Accessibility Policies that acknowledges the use of social media platforms, and standalone policies for Social Media use and commenting. Each of these policies should identify the ways in which a government entity plans to use social media, how it complies with records law, and how it handles comments from other platform users. This toolkit provides clear and consistent guidance to government entities in Massachusetts seeking to use social media sites (Executive Office of Technology Services and Security, 2023). However, additional language in the toolkit reveals a lack of understanding of digital preservation techniques to apply to this complex records environment. After acknowledging that “while third party social media providers will most likely save your content for some period of time, they generally will not save it indefinitely,” the toolkit suggests taking periodic “snapshots” of content to meet Public Records Law obligations. This is not the only approach to social media records preservation, nor does it capture the unique features and types of user engagement that define each popular platform.

**METHODS**

This project examined the websites of 351 municipalities in Massachusetts to understand municipal use of and regulation around social media platforms. The list of cities and towns was derived from the Secretary of the Commonwealth’s website (Secretary of the Commonwealth of Massachusetts, n.d.), modified only to exclude municipalities which no longer exist (primarily due to annexation). Analysis was performed in Spring 2022 and reflects the publicly available information for each municipality available at that time.

From the working list of cities and towns, each local government website was searched and analyzed across a number of attributes. After determining if the municipality maintained an active social media presence on popular social media platforms (typically Facebook, Twitter, or Instagram), the next step involved searching and reading through the municipal website for a publicly-available Social Media Policy. While some policies were clearly linked through the site navigation or menus, other policies were more difficult to locate; these tended to be policies published as PDFs and linked to download from a webpage as opposed to a dedicated page on the website for the policy in question. Dates of adoption and any updates were noted, where present.
Each publicly available social media policy was further categorized across three characteristics of interest: whether the policy specifically references the Massachusetts Public Records law or another records management statute, whether the policy directly states that social media content should be retrievable by the public, and whether the policy specifies that a given municipal government has a commercial contract with a third-party social media digital archiving subscription-based service.

RESULTS
From the largest city in Massachusetts, Boston (pop. 675,647) to the smallest town, Gosnold (pop. 70), municipal governments across the commonwealth exhibit a broad range of approaches to social media use and policy. While relatively few municipalities in Massachusetts have publicly available social media policies, many municipalities maintain accounts on one or more social media platform. In total, 249 cities and towns had at least one social media account discoverable either through government websites or via Google search as of May 2022. This figure represents 71% of municipalities in the Commonwealth. Despite this, many of these local governments do not have publicly-available social media policies on their websites, as shown in Figure 1 below. Of the 351 municipalities in Massachusetts, only 87 (25%) have publicly-accessible policies which could be found on their city or town website. The policies with dates of adoption (n=76) included in their published form demonstrate that these policies were adopted between 2012-2021, coinciding with the rise in prominence of popular social media platforms like Facebook, Twitter, and Instagram. All of the 87 municipalities with social media policies use at least one platform, leaving 162 active on sites like Twitter and Facebook without publicly available policy outlining their use of these digital tools. These municipalities engage with citizens and post information about their communities but without the policy infrastructure recommended in the “Social Media Legal Guidance Toolkit.” As a result, it is not clear if, or how, these municipalities are managing social media records, and if they are in compliance with state Public Records Law.

Figure 1. Municipalities in Massachusetts with Social Media Policies

In terms of the analyzed attributes of these publicly available policies, a majority (72%) directly reference Massachusetts Public Records Law when defining the scope and mandate behind social media policy development. Only 18% of the policies examined in this project mention ongoing access to social media posts or digital preservation efforts being undertaken by the given city or town. These results are illustrated in Figure 2 below.
Of the 351 municipalities in Massachusetts, this project discovered just one website confirming that the town utilizes a third-party social media preservation and management service. The town of Westford (population 24,643), located approximately 30 miles northwest of Boston, employs a service called Pagefreezer to archive and provide access to Facebook and Twitter posts (Town of Westford, 2023). A screenshot of the town of Westford’s website, seen in Figure 3 below, illustrates how the community provides access to older posts from Facebook and Twitter accounts associated with the town government, Library, Fire Department, Police Department, and other municipal agencies. While the explanatory text does not mention Pagefreezer directly, each icon next to an account links to a hosted Pagefreezer page. Of all the cities and towns in Massachusetts, this was the only “Social Media Archiving” page which clearly indicated that a community made use of third party preservation services to fulfill their obligations under Massachusetts’ records law. If other communities use these services, they manage the records internally and refer to them as needed based on public records requests.

The 87 municipal social media policies vary in their approach to regulating social media use in municipal governments. Many policies directly acknowledge the fact that social media posts are considered public records under Massachusetts law, including Southborough whose policy states “Official Town Social media sites will contain communications sent to or received by Town employees or officials, and are thus considered Public Records...
under Massachusetts law. Department Heads shall retain a copy of all social media content in accordance with Public Records Retention Schedules” (Town of Southborough, 2018). The primary topics covered in the policies relate to other issues related to social media, such as the relationship of the municipal government to the platform’s Terms of Service, the approach taken to comments on government posts, content review of municipal posts, and the ways in which local governments understand the First Amendment as it applies to social media sites. These are all important questions that demand the attention of government officials actively using social media, but do not speak to the retention and preservation concerns that arise in the space between Public Records Law and social media management in practice.

Looking more closely at these Social Media policies, some patterns emerge upon comparison. A number of sentences and clauses appear in more than one policy, often related to records retention and access. For example, Lunenburg, Merrimac, Plainfield, Provincetown, Topsfield, Truro, Upton, and West Boylston specify that social media content “must be able to be managed, stored and retrieved…” under state records law (Town of Lunenburg, 2017; Town of Merrimac, 2017; Town of Plainfield, 2017; Town of Provincetown, 2018; Town of Topsfield, 2019; Town of Truro, 2018; Town of Upton, 2012; Town of West Boylston, 2012), further specifying that e-discovery law may apply as well, should the town government be party to a lawsuit in which social media posts play a role. Other shared language across policies in Boston and Rutland demonstrates the efforts of these municipalities to balance the context of the post while prioritizing access into the future, noting that social media records should be managed “in a format that preserves the integrity of the original record and is easily accessible…” (City of Boston, 2014; Town of Rutland, 2015). While both of these examples demonstrate the commitments of municipal governments to responsibly and legally managing social media records, they do not offer specific insight into how records will be maintained over the long term.

Other policies similarly articulate social media retention mandates but do not make it clear how they plan to maintain access to these records over time. The City of Cambridge’s Social Media Policy includes the following clause related to retention: “Any Content maintained in a Social Media format…may be a record subject to public disclosure….The department site administrator will maintain records in accordance with Massachusetts public records and record retention laws, rules, regulations, and policies” (City of Cambridge, 2013). What is absent from this clause is how these records will be maintained, whether using internal documentation, screenshots, third party apps, through reliance on the continued existence of the platforms themselves, or other means.

At least five municipalities (Fairhaven, Merrimac, Plainfield, Upton, West Boylston) incorporate language related to digital records retention for social media posts adapted from the Massachusetts Social Media Legal Guidance Toolkit (Executive Office of Technology Services and Security, 2023). The following text appears, with some variation, in the Social Media policies for these towns:

Note that while third party social media providers will most likely save your content for some period of time, they generally will not save it indefinitely. To the extent their policies are inconsistent with Public Records Retention Schedules, the Town or department should retain copies of social media posts such as by printing or otherwise storing periodic “snapshots” of the social media sites. (Town of Fairhaven, 2015; Town of Merrimac, 2017; Town of Plainfield, 2017; Town of Upton, 2012; Town of West Boylston, 2012)

This language is notable for a number of reasons. It suggests that these municipal governments have done their research when crafting local Social Media policies and consulted the advice and best practices made available at the state level. Given the potential legal risk for public sector institutions if they do not adhere to records retention schedules, this approach makes sense. However, the specific advice offered here reflects the challenging current state of social media digital preservation and a return to earlier eras of records management practice. Social media posts generated by governments are public records under the control of privately operated platforms. Their dynamic nature and unique embeddedness in networked platforms suggest a need for new approaches to digital preservation and archiving in these areas.

The publicly available social media policies from Massachusetts municipal governments show a set of public sector institutions grappling with the particulars of how to comply with public records laws in a rapidly evolving digital environment. The challenges for public sector entities operating on privately operated social platforms require that they improvise and employ whatever methods they can to meet their statutory obligations. Without clear procedures and policies from the platforms themselves defining their relationships to government agencies using their sites, these inconsistent approaches are likely to persist. Still, for the many municipalities in Massachusetts operating social media accounts without publicly available policies, taking smaller actions such as drafting and posting policies governing social media use could reduce risk, increase transparency, and set expectations for constituents and other users encountering government accounts online.
DISCUSSION
Municipalities use social media for the same reasons many private citizens, corporations, and other organizations engage on these platforms: to connect directly with followers and communicate via easily accessible channels. However, unlike other type of social media users, local governments are bound by public records laws to manage these records in ways which promote transparency, accessibility, and evidence of government activity. As the results in the previous section show, a majority of the local governments using social media in Massachusetts do not have policies governing their use which they share with constituents. This suggests that there is much work to be done in local government to meet their obligations under the law to manage social media records alongside other government records produced in the pursuit of a public mission, to inform citizen of government activities, and to engage directly with constituents.

How many municipalities in Massachusetts would be prepared to respond to a records request or inquiry under the Commonwealth’s Public Records Law? Based on the policies examined in this paper, some governments might struggle to locate social media content that is not still available on the platform in question or has not been screenshotted. Many social media sites including Twitter and Facebook allow users to download their data from the platform for local management or storage, however little evidence of this practice was seen in the available policies for Massachusetts municipal governments. Information on collecting data from Facebook, Twitter, and other platforms is more widely shared in the social science research community than in government, as multiple research methods books provide information on how to harvest data from social media sites (Flick, 2018; McCormick et al., 2017). This feature of social media platforms was absent from state guidance despite being a valuable, low-cost, and available option to extract some platform data and retain it in formats that municipal archives may be able to manage.

The official guidance from Massachusetts’ Executive Office of Technology Services and Security includes screenshotted as a potential method for preserving social media posts. While this may be a short-term strategy for retaining content from social media platforms, it represents a step backwards in terms of digital preservation practice, recalling Duranti’s (2010) critique of “print and file” as a records management strategy. Social media posts are complex digital objects; using screenshots to capture these records flattens them and fails to account for key features which make these platforms so distinct, including ongoing engagement information, embedded media, lists of followers, and the nature of the social feed itself.

While only one municipality (Westford) was found to share links to third party social media archiving content, more local governments across Massachusetts may be utilizing these services. For its part, ArchiveSocial maintains individual pages on its corporate website outlining the specifics of all 50 state records laws and identifying how its software can help organizations comply with these regulations. The emergence of software providers into this space has not been studied or examined by the archival or digital preservation community and should be the subject of future research into social media archiving. How do these companies work with platforms to preserve posts? How do they leverage API access and what records are they storing on computing infrastructure they control? A recent study by Borji et al. (2022) compared features directly from the public documentation ArchiveSocial, Pagefreezer and Smarsh share online (ArchiveSocial, 2023; Pagefreezer Software Inc, 2023; Smarsh, Inc, 2023). These three products remain among the most popular offering social media archiving services today, but changes to platforms are likely to result in ongoing changes to this nascent preservation services landscape.

The ongoing product and policy changes across social media platforms have the potential to significantly affect the ways in which local governments produce and manage records on social media platforms. One recent example, the changes made by Twitter to its API, may affect some preservation practices being employed by government or apps they use to comply with records laws (Benton, 2023; Fung, 2023; Ledford, 2023). These changes may affect the commercial social media archiving services as well, with both loss of functionality and increase in cost as potential outcomes of the latest round of updates by Twitter.

This study was exploratory in nature and focused on Massachusetts due to the public records legal infrastructure and bounded nature of municipalities in the state. While this narrow scope is a limitation of the project, future work can address this through broader examinations of social media records policy across the United State and internationally at different levels of government. An additional limitation of the present study is that it focused on standalone social media policies in Massachusetts municipal governments, not larger records management policies or schedules. The intention behind this was to focus on how governments directly addressed the challenges of managing social media records, and future work in this area should seek to understand social media records management as part of larger information management requirements for different levels of government.

CONCLUSION
This study examined the ways in which city and town governments in Massachusetts manage social media records, as illustrated by their publicly available social media policies. Few municipalities that use social media have such
policies, and those that do exist provide little specificity around how social media records are actually managed and retained. This situation represents a risk for these governments if they should be unable to fulfill a public records request, and it represents a further risk for the public as social media posts show what the government shares with citizens, when they share, and how other platform users interact with public sector content. If one of the popular social media platforms were to go dark, would municipal governments have access to backup copies of posts or would they be left, like the vast majority of users in such a hypothetical scenario, without any documentation or evidence of what they posted on the site, who replied, how many accounts followed theirs, and what the overall experience was like using one of these sites in an era where millions of eyeballs were pointed at robust social feeds?

Social media archiving is still in its infancy. While multiple stakeholder communities have interests in ensuring that social media records remain available into the future and can remain viable outside of the platforms on which they were created, few projects have demonstrated an ability to do this work at scale. The existence of third-party commercial software vendors developing software to address this problem and allow a variety of public and private sector organizations to comply with records and information management law speaks to the urgent need in information-intensive organizations for solutions to this challenge. Further work on this topic is needed to understand the shift in practice happening across the public sector for social media records.

The Public Records Law in Massachusetts contains clear, strong language mandating social media records be treated like any other government record. However, the dynamic nature of social media posts means that they resist digital preservation techniques that have become standard practice for static media such as digital photographs, PDFs, documents, or data files. Currently, records managers and archivists seeking to preserve social media posts have few options, each of which have their strengths and limitations. In the absence of widely accepted standards for social media digital preservation, municipalities are left to figure things out on their own, using screenshots, downloads, and potentially third-party services. Because state public records law requires social media to be retained, this will continue to be an issue until such standards emerge. While the current study was limited to Massachusetts, these challenges are not unique to one state, or even to government. A lack of social media preservation approaches is an ongoing concern for the digital preservation and archival communities, as well as for researchers in disciplines that may want to examine these materials in the future. The risks associated with losing access to social media records threaten to obscure our view of current events in the years to come, when historians will seek to analyze our times using all available records. If they disappear from the web, social media records will contribute to a digital dark age resulting from inconsistent web archiving practice that dates all the way back to the earliest days of the internet (Brand, 1999; Milligan, 2016).

As the social media landscape continues to shift along with the fortunes of the companies that develop and operate these platforms, digital preservationists, archivists, and records managers will need to stay informed about how social media records are created and stored. Practitioners working in these areas should seek to be a part of conversations about what archiving for social media should look like, and how records may be able to remain legible outside of their platforms of creation. As information professionals with an eye towards future use by people who have yet to be born, it is our job to articulate our perspective and push for mechanisms to preserve social media records so people in the future will be able to look back at the internet as it was and understand how vastly different types of users, from celebrities to small town Public Works Departments used these platforms.

ACKNOWLEDGMENTS

The author wishes to thank Rachel Starr and Kate Grant for their contributions preparing data for this project, as well as the Simmons University School of Library and Information Science for supporting this work through the Graduate Student Assistantship program.

ABSTRACT
Research data sharing is embedded in policies, guidelines and requirements commonly promoted by research funding organizations that demand data to be “as open as possible, as closed as necessary” and FAIR. This paper discusses the challenges of balancing privacy protection with data sharing in a PhD project involving long-tail, small-sized qualitative human subjects’ data. Based on experiences and feedback from project participants, we argue that privacy protection is about respecting the participants and their self-image. This can be achieved through dialogue and involvement of the participants building on the principles of shared stewardship. Further, we suggest that de-identification and plain language consent materials are better at protecting privacy than anonymisation, which in a digital data environment is difficult to achieve and not necessarily a sensible approach for qualitative data, where the gold is in the details. The literature indicates that it matters to participants whether data are reused for research or other purposes, and that they trust the institutions. This supports our claim that research data services must find better solutions for restricted sharing when necessary.

Data Sharing, Research Ethics, Privacy, Qualitative Research, Research into Practice

INTRODUCTION
Open research data and sharing of research data is a key pillar of Open Science, promoting transparency and trust in scientific institutions and the advance of scientific research (UNESCO, 2021). Institutional and international policies for open science increasingly require datasets collected for the purpose of research to be made available “as open as possible, as closed as necessary” (European Commission, 2016), with the aspiration of making them FAIR (Findable, Accessible, Interoperable, and Reusable) (Wilkinson et al., 2016).

Researchers conducting human subjects’ research must abide by research ethics guidelines, national and international data legislation (Ursin & Bentzen, 2021), and by university and funding agency policies (The Norwegian National Research Ethics Committees, 2014). For instance, the Belmont Principles that govern human subjects’ research draw attention to 1) respecting human subjects, by use of informed consent and protecting privacy; 2) protecting research subjects from the risk of harm; and 3) addressing issues of justice (U.S. Department of Health, Education, and Welfare, 1979). However, each of these three imperatives is made more complicated by opening human subjects’ data: 1) human subjects may struggle to imagine how data about them could be used in new contexts, undermining their ability to give truly informed consent for reuse (Wilbanks, 2014); 2) their data could be combined with other available datasets to generate new insights about them that could be used for harmful purposes (Ohm, 2014); 3) marginalized groups of people may be more liable to harms from misuse of data about them (Carroll et al., 2020).

Balancing the realization of the benefits of Open Science with adherence to ethical and legal standards is a “problem of many hands,” that require action by many research data curation stakeholders and at all stages of the research lifecycle. Decisions taken early on in a research project have significant implications for subsequent possibilities for sharing and for privacy protection. For instance, researchers need to design and carry out data collection processes with sharing in mind, choosing metadata schema and creating documentation that will enhance reusability of the dataset, while carefully minimizing the data they collect to enhance privacy protections (Tibor, 2021, p. 54). However, little training currently exists for social science researchers about how to approach these topics effectively. Data management plans, increasingly required by funding agency, have the potential to help researchers in designing and carrying-out data collection, but only if requirements for these plans are well-formulated and effectively enforced. A third key group of stakeholders is research support service providers, for instance in university libraries and disciplinary data repositories, who can provide consultational and informational services, but who require training and resources to provide adequate support to researchers.

This paper builds on the first author’s PhD project, a study of 24 expert stakeholders involved in research data curation in Norway (L. Kvale, 2022), to explore the challenges in making social scientific human subjects’ data as open as possible while respecting study participants’ privacy. The study data were collected through a modified Delphi study, comprising interviews (n=48) and surveys (n=24). The first author aimed for these data to be made as open as possible in line with open science expectations from domestic science funding agencies (The Research

86th Annual Meeting of the Association for Information Science & Technology | Oct. 27 – 31, 2023 | London, United Kingdom. Author(s) retain copyright, but ASIS&T receives an exclusive publication license.
Council of Norway, 2020), while working within domestic and international ethical and legal constraints, such as the European Union’s General Data Protection Regulation (GDPR) and Norway’s Personal Data Act and research ethical guidelines (GDPR, 2016; The Norwegian Personal Data Act, 2018; The Norwegian National Research Ethics Committees, 2014).

It is this tension we explore through addressing the following question:

**Can sharing of non-sensitive de-identified human subjects’ data be practiced while respecting the research participants’ right to privacy?**

Drawing from analysis of feedback from participants, we provide experienced-based recommendations for researchers and data management professionals to handle the difficulties involved in balancing opening data with respecting privacy. There is no one size fits all for translating policies for open science into research practice. The challenges researchers encounter when dealing with human subjects data, have until recently not been addressed in the literature on research data management. De-identification describes the removal of identifiers that are either linkable or directly identifiable. De-identified interview transcripts could have value for reuse for instance, in teaching research data curation to information management professionals, to facilitate future research in the area of scholarly communication, and historically as a documentation of strategies and decisions in the digitalisation of research, or simply for machine learning purposes.

Our study is relevant for research support service providers struggling to balance expectations and requirements of sharing with protection of privacy and research ethical norms, providing a case of how this can be solved. It is also relevant to researchers, in particular researchers conducting research in Europe or collaborating with researchers in a European context, as an example of an approach to how open sharing of interview transcripts and personal privacy is perceived amongst expert stakeholders of data sharing. We recognize that while general norms for privacy and research ethics have a global scope, they are perceived and implemented in quite different ways. Subsequently knowledge of these differences is crucial for international research collaborations.

**PREVIOUS RESEARCH**

Research participants’ attitudes towards open data sharing has not yet been explored extensively. A study based on interviews with qualitative researchers, Institutional Review Board members and data curators in the US revealed that researchers are the least knowledgeable and are often unfamiliar with the concept of sharing qualitative data in a repository (Mozersky, Walsh, et al., 2020). Several countries have traditions of sharing of qualitative data via restricted access repositories with different standards for de-identification. However following the argument of open science as a way to foster public trust in research (DuBois et al., 2018; UNESCO, 2021) it would benefit science to share more qualitative data openly with the consent of the research participants.

Current studies of data sharing and reuse explore restrictions on sharing and highlight how the type of reuse matters to research participants (Hardy et al., 2016; Mozersky, Parsons, et al., 2020; Shah et al., 2021). Mozersky, Parson and colleagues (2020) find that the majority of the research participants were positive to sharing of qualitative data given that the sharing and reuse is limited to research purposes and that their identity is concealed. Shah and colleagues find similar attitudes towards sharing and reuse of health data; the research context matters to the participants (Shah et al., 2021). Hardy and colleagues (2016), on the other hand, argue that sharing and reuse of the data collected would be unethical as the conditions for access to the participants were that certain issues would not be investigated even if the data could have provided the possibility. This is echoed by researchers expressing concerns that it would be unethical to share qualitative data collected in a relation of trust without an element of informed consent (DuBois et al., 2018). While researchers refer to the relation of trust between researchers and participants, the participants generally trust institutions rather than the individual researchers (Guillemin et al., 2018).

Within the scholarship of human computer interaction, privacy by design is used to describe how technology can be designed in compliance with privacy (Hoepman, 2021). This way of thinking privacy embedded in the methods and data collection is also useful when designing and conducting research projects. It does however require awareness of different perceptions of privacy. Gürses group privacy by design in three categories according to how privacy is understood: 1) hard privacy approaching privacy as confidentiality, 2) soft privacy addressing privacy as control, and 3) contextual privacy addressing privacy as a practise where negotiations of social boundaries are taking place (Gürses, 2014). Later privacy by compliance has been added, referring to how GDPR has led organizations to aim at compliance with the corresponding jurisdiction rather than providing individuals with control over their data (Fiebig et al., 2022). The conflict between GDPR and data sharing initiatives within health research has been adressed by Ursin and Bentzen (2021) who call for harmonization of data protections standards to allow global sharing of research data.
In qualitative research, member checking is sometimes used as a technique to validate results by either returning interview transcripts or analysis of the data to the participant for comments, corrections and verification (Creswell & Miller, 2000; Forbat & Henderson, 2005). Karhulathi (2022) propose using member-checking for sharing qualitative data, using co-curation as a term to describe how member-checking allows participants to edit transcripts as part of preparing them for open sharing. While there are studies on how participants approach transcripts when asked to review these for errors (Birt et al., 2016; Carlson, 2014; Forbat & Henderson, 2005), the authors are not familiar with literature addressing participants’ experience of member checking for publication. Also Huma and Joyce highlight the lack of expertise amongst researchers and ethical comities on how to proceed with sharing of qualitative data while safeguarding research participants (Huma & Joyce, 2022). A synonym for co-curation is shared stewardship, a concept drawing from studies of indigenous data sovereignty, that embodies the data subjects rights and interest in their material (First Archivist Circle, 2007; Leopold, 2019). Within research data management, indigenous communities have developed the CARE principles to address their interest and rights over data governance and reuse (Carroll et al., 2020), within which shared stewardship conceptually embeds the practice of shared control and governance.

METHOD

This paper describes the process of sharing data from a Delphi study, which is characterised by using experts on a particular topic as participants and collecting data in multiple rounds focusing on solving an issue or developing a policy (Ziglio, 1996). A Delphi study is designed to find agreements and common understandings amongst involved stakeholders. In a rapidly developing domain such as that of data sharing, the Delphi method offers a way of systematically collecting solution-oriented opinions. A Delphi study typically contain three sequential phases: 1) the exploration phase, 2) the evaluation phase, and 3) the concluding phase (Ziglio, 1996). In each phase data are collected and analyzed and the intermediate results are used in the development of the next phase of data collection.

Participants were drawn from four stakeholder groups involved in research data sharing: policymakers, infrastructure providers, research support staff, and researchers. 24 participants took part in the study, which makes it similar in size to other Delphi studies in library and information studies (Lund, 2020).

The data collection took place in three phases (Figure 1), where the first and last phase involved conducting interviews (n=48.) First phase interviews were about one hour long, while last phase interviews lasted approximately 30 minutes. At the recruitment stage, participants were informed of plans to make interviews openly-available in a public repository. The interviews were transcribed by the first author, yielding 313 pages of transcripts. During transcription, the first author de-identified participants by removing directly identifiable information such as names and workplace. Nevertheless, most of the participants remained identifiable as they in many cases represent the only domain expert with their background and experience. Transcripts were sent back to the participants for verification, and participants were also asked to mark sequences of the interview they did not want openly shared (Birt et al., 2016). These sequences were included in data analysis but removed from the published transcripts, extra care have been taken to conceal the participants identity where quotes from marked sequences are included in this and other publications from the study.

![Figure 1. The research design (L. Kvale & Pharo, 2021)](image)
Following interviews, participants were given the opportunity to indicate their consent for sharing their data openly. Feedback on a draft version of the consent form given to participants was solicited from the Norwegian National Privacy Advisors’ Services (NSD/SIKT) which had no objections or comments on the form. In this consent form, the participants were also asked how they felt about participating in the study (L. Kvale, 2021). 21 participants granted permission to share all or parts of their data, while three participants did not respond to the consent form so their data were not shared.

The aim of sharing de-identified data and the review of transcripts were discussed with the participants multiple times throughout the study, and multiple participants expressed interest in, and opinions on, these topics. Initially, the plan was to anonymize the data. As the first round of interviews were transcribed, it became evident that the data could not be anonymized, even with directly identifiable information removed. Information about stakeholders’ roles, selection criteria, and participants’ expressed opinions and experience made it likely that some participants could be identified readily. When reading the transcripts, the first author could recognize participants based on their language and metaphors or by descriptions of their work with research data.

True anonymity is difficult to achieve, and may not always be the most appropriate approach for privacy protection; instead, an approach that focuses on what needs to be protected and how context shapes human subjects’ privacy expectations is preferred (Barocas & Nissenbaum, 2014). The first author followed this approach by informing participants about the aim to share data in an open repository, and allowing them to review their data and select what to share openly.

Table 1. Examples of methods related qualitative codes used in the analysis of the interviews

This paper builds on the discussions of methods in the first author’s PhD thesis (L. Kvale, 2022). The findings are derived from different parts of the study including the interviews, material retracted from sharing in the interview transcripts, the first author’s notes taken after each interview, and comments provided by the participants in the consent form for data sharing. This material has been structured and analysed qualitatively by exploratory thematic coding (Saldaña, 2016) during the first three phases of the study (Figure 1.), followed by thematic grouping (S. Kvale, 2007) and meaning synthetization as part of the integrated analysis (Creswell & Plano Clark, 2018) after data collection was completed (Figure 1, phase 4).

In the paper, quotes from each participant have been assigned one of the following pseudonyms, suggested as gender-neutral by Google: Andrea, Leigh, Ashley, Frankie, Jackie, Parker, Sam, Linden, Bobby, Chris, Dylan. In some cases, pseudonyms have been associated with professional roles; in other cases, they have not where the risk of reidentification was judged to be too high.

FINDINGS
The findings raise awareness about how different research participants experience issues related to privacy in diverse ways, and how researchers need to address these differences as part of privacy protection and ethical considerations regarding data sharing. We have categorised our findings into two parts: 1) how participants control their self-presentation through reviewing the de-identified data, and 2) how the participants experience data sharing.

Control over self-presentation by reviewing de-identified data
When reviewing their transcript, each participant could select parts of the interview that were not to be published in the open dataset. Analysis of what participants requested removed from the transcripts before publishing show two tendencies, concealments of a) relational conflicts, or b) personal identity.

Concealments of relational conflicts or criticism of organisations
Participants requesting removal of text containing descriptions of conflicts in collaborations or criticisms of their own organisations. For instance:

“We collaborate with [other research support services at the university] and there are different cultures, different attitudes towards different things, and when there is a need for distribution of responsibility it is typically different perspectives on who should do what and who should be responsible for what. So, this can occasionally be quite demanding.” (Leigh, research support)
The quote from Leigh refers to the challenges of collaborating with other research support services in the university, a challenge echoed by several other interviewees. However, this participant did not want others to know they had discussed these challenges due to concerns it could negatively affect an existing collaboration.

Two other interviewees, Ashley and Frankie, requested removal of text that could be perceived as damaging to their own, fragile organizations, as illustrated here:

“Right now, we are just trying to promote our self and our services, we are in a situation where we need to make sure we as organisation are still relevant”. (Ashley)

“I would ask you to be quiet about these things for a while as I do not yet know to what extend this is public knowledge” (Frankie)

Both quotations describe organizations in limbo, discussing dilemmas in making their services relevant to users and describing changes that are not yet formalized. Frankie’s quotation could reflect negatively on them for speaking out of turn by revealing confidential details about their organization, while Ashley expressed concerns about publicly underestimating the value of their organization in a competitive environment.

These three quotes describe different types of tensions in the organizations where the participants work. Removing these details from the published data obscures part of the tension within organizations regarding directions and responsibility for data management services and tools. In all three quotes the participants opened up to the interviewer and shared their thoughts in confidence, based on trust between the interviewer and interviewee. This closeness places an ethical responsibility on the interviewer, which is fulfilled by sharing these quotes with as little concealment of personal identity

The second tendency was several participants’ requests to hide their identity further by removal of specific information regarding their work. This tendency included terms such as, “university library,” “data curation,” and “language researcher.” The possibility of identification was something the participants showed understanding of, as the researcher Andrea points out:

“If people know that you came to this institute for an interview with people who created a DMP, people who know that I am here on a fellowship, they will find out that these are my answers. But others will not know it.” (Andrea, researcher)

Jackie, a high-profile researcher, removed multiple details about their research practice that could make them easily identifiable. Still, enough details remain for someone with close knowledge of the domain to potentially identify Jackie.

Parker, another researcher, revealed a reluctance to comply with privacy requirements at an earlier point in their research career (L. Kvale & Darch, 2022). Revealing Parker’s identity could potentially cause harm to their reputation as researcher. Parker requested many of the details which could identify their identity to be removed from the transcripts. A combination of details reported in published articles, combined with the information retained in the transcript, could, however, still make Parker identifiable. The text Parker removed, along with dialogue with the first author, indicated that Parker did not wish to be identified in the open dataset. In this case, the first author decided not to publish the interview transcripts at all, despite Parker’s consent to publication, to protect Parker’s dignity and integrity.

In the published transcripts, several other study participants are likely to be identifiable by someone with knowledge of their research. Further, knowledge of selection criteria for study participants, as described in existing publications(L. H. Kvale, 2022), could also contribute toward identification of participants.

Participants’ experiences of sharing de-identified data

During the final round of interviews, several participants shared their opinions about their experiences of reviewing their first round interview transcripts and sharing their data. These opinions were noted in the first author’s interview notes. This section first addresses how participants described the experience of reading their transcripts before considering participants’ and perceptions relating to sharing the study data. Participants diverged in how they experienced the process of making their data open. Some expressed that reviewing their own words made them feel vulnerable, while others appreciated the possibility to review transcripts. 13 participants did not remove any text but consented to publishing the transcript in full.

Personal emotional experiences

Having one’s conversation laid out in text gives a sensation of exposure. One participant, Linden, mentioned how they felt “so stupid” when reading their incomplete sentences. In her notes, the first author describes being surprised about Linden’s reaction:
“I was surprised that Linden, of high status, position and with extensive research background experienced [reading their transcript] so harshly. I assumed that my participants are all aware of being intelligent, still reading themself on paper is experienced by Linden so brutally. Linden described a real emotional breakdown at ‘sounding so incoherent.’” (notes from interview with Linden, policymaker)

This sentiment was echoed in several second-round interviews:

“After the interview, they talk about the discomfort of reading themself orally on paper, with lines of reasoning with no clear start or ending” (notes from interview with Sam, researcher)

Other participants highlighted the burdensome workload of reviewing their transcripts, including the time taken correcting grammatical errors and understanding sentence fragments. One of the researchers suggested that more elaboration of the text in the transcripts would have been useful to increase readability of the interview transcripts:

“One recommendation for later projects is to modify transcripts so that they consist of complete sentences; this would not reduce the truth content in the reporting… and would probably increase the understanding and ensure more unambiguous interpretation.” (Sam, researcher) ([author], 2022 p 90)

In this case the transcripts were verbatim, including filler words, false starts, incomplete phrases and off-topic comments. Editing the transcripts so that each sentence had a start and an end would increase readability for the participants when going through the text.

Chris points to how the review of transcripts is overwhelming for a research participant:

“As participants we can all say: now this is getting too demanding. That is a right the participant has, and in that way all informants have absolute security. But on the other side take qualitative methods and informants, if every quote has to be approved by the informant. Then the informant is interfering with the analysis in a way that would interfere with the research quality. So, something will have to rely on trust to the researchers understanding of the issues explored, and I don’t think it has to be that difficult” (Chris, Researcher)

Chris was themself considering dropping out of the study as they perceived the workload in participating high, at the same time as they did not consider themself an expert. Both one of the policymakers, Billie, and researcher Criss address how privacy protection and mutual trust is important in regard to requirement of participants. This trust also entails the protection from unwanted negative consequences, when participants express uncertainty or feel they don’t really have reflected enough on a topic. In a broad yet specialised topic such as data sharing, inducing the voice of multiple stakeholders were important to include the opinions of researchers “who do not think of data management plans 24/7” (Parker).

Context related emotions

The research support staff Bobby and Dylan described feeling hesitant about publishing their transcripts, Bobby points to how research as context makes them think differently about their statements. Awareness of how their statements are part of a dataset to be coded, analysed and discussed in publications makes Bobby more sceptical to sharing the transcripts in full. They again find this experience useful in their work with data management services. For some, this was their first hands-on encounter with qualitative research, and expressed that their experiences as research participant would making them more cautious in advising anonymisation as strategy for researchers to share qualitative interview data in the future. The self-image the research participants felt embedded in interviews as research data, also increased awareness on the importance of consent and dialogue with participants around sharing for ethical reasons. It also provided awareness on the relation of mutual trust between researcher and participant, by first-hand experience. This was shared by research support staff both in the context of the second interview and elaborated on in the consent form for data sharing:

“And this was quite an interesting experience for my own sake, when I went through the interview and thought – do I stand for this? Do I want this removed?” (quote from the interview with Bobby, research support staff)

“Dylan also shared thoughts of why they might not want to share the transcripts. The fact that they make several claims regarding issues they might not know that much about, things that come up in the conversations but which they haven’t actually reflected on.” (Notes from interview with Dylan, research support staff)

“It is interesting to be in the information position and relate to one’s own statements. Even if the information I have provided is in no way sensitive or provoking, I feel some hesitation in accepting publication of the interview material, even in de-identified form. This is interesting and will be a useful experience to carry along with in the work with support services for those working with qualitative data”. (comment in the consent form from Bobby, research support staff) (L. Kvale, 2022, p. 91).
Bobby also addresses how they experience contextual differences from expressing something in their private sphere, awareness of the data being qualitatively analysed and deiminated in publications makes them hesitant about publishing the transcripts in full. For Bobby the control of what information to share in which context is a central part of their privacy perception:

“When we discussed anonymizing and sharing the research data, as soon as you are an embedded part of the analyzed material, in a way you get categories to yourself, then I feel much more skepticism toward getting this published. Even if I could have said many of the same things in my private Facebook account or in presentation, but something about being part of a study makes it different.” (Bobby, research support)

Elliott addresses how the experience of being a research participant provided a new perspective on data sharing:

“Interesting theme and interesting question, which initiated reflections and ideas. Considering my work, participating in the study felt relevant and useful.” (Elliott, research support)

This aspect of participating in a research study was shared also Bobby and Dylan who like Elliott work in research support services advising researchers on data sharing as part of their job. Sitting in the research participant chair made them more aware of how sharing is perceived from the participant’s side of the table. As research support services, research participants are not part of their sphere, still they are likely to advice researchers on how to best balance privacy and data sharing in research.

DISCUSSION

To live up to the ideals of Open Science and at the same time securing research participants’ privacy and integrity is challenging when data are collected using qualitative interviews (de Koning et al., 2019; Mozersky, Parsons, et al., 2020). We find that anonymization of interviews within a small community of domain experts would require the removal of significant amounts of useful contextual information, in addition to modifications of expressions that make individuals identifiable. For qualitative data this approach could easily ruin the data quality and hence the value of the shared data.

Removing context and details in qualitative data is likely to lower the quality of the data shared for future qualitative analysis. We have studied stakeholders involved in data sharing curation and demonstrated how removing details about their practices has revealed the complexity of creating anonymous qualitative data. Anonymizing data is often presented to qualitative researchers as an option for making it possible to archive and share qualitative data openly (Huma & Joyce, 2022; Mozersky, Parsons, et al., 2020), this was not perceived as a realistic possibility in this material.

Anonymous data can be shared without conflicting with the GRDP requirements. Still research ethical requirements for research on human subjects would apply (The Norwegian National Research Ethics Committees, 2014). Scholars have previously argued that sharing of human subjects data from health research is not compliant with GDPR (Ursin & Bentzen, 2021). Analysis of the interviews from the current project made it clear that identification of participants would be possible even if directly identifiable information such as names and affiliation were de-identified.

The debate regarding anonymity shows that it is hard to achieve, and not always the appropriate approach to privacy (Barocas & Nissenbaum, 2014). Gürses identifies multiple different approaches to privacy (Gurses, 2014), highlighting how privacy are different things to different people, and that GDPR has introduced a compliance approach to privacy which does not aim at providing individuals with control of their data (Fiebig et al., 2022). According to Nissenbaum and Barocas, it is important to discuss what privacy is protecting, and the context in which human subjects data are managed, rather than focusing on finding solutions to ensure anonymity. Our study shows it is possible to re-identify research participants in qualitative interviews, either by close knowledge of the domain investigated or by access to additional data. As qualitative researchers we continuously strive to balance details with confidence. Open sharing in a repository while guaranteeing participants anonymity in the interview transcripts is often not possible. Therefore, the first author pursued a different strategy of consent through dialogue and review of the data with each participant building on the principles of privacy in context (Nissenbaum, 2010).

To balance sharing and privacy without focusing on anonymity, the first author selected a strategy of informing participants and allowing them to review and select what to share. This, we believe, is a fruitful way in reaching the goal of making research data “as open as possible, as closed as necessary”. Member-checking and the relation between researchers and participants can be used as an asset to achieve data sharing (Karhulahti, 2022) and enable shared stewardship. It does, however, raise some new challenges. The findings show that reviewing transcripts is not as straightforward as it can appear, further the removal of elements in the text can affect adepts’ attempts at reanalysing the material, and, finally, the usage of context and quotes in publications can come in conflict with aims at protecting the participants identity.
Soundness, transparency and accessibility are important Open Science principles, but, as we have shown, they are not easy to support in qualitative research (Huma & Joyce, 2022). Huma and Joyce argue that the contextual dependency of qualitative data “warrants a rethink of whether and how such data can ever be reused in secondary analyses” (Huma & Joyce, 2022). We will, on the other hand, argue that transparency with respect to how conclusions have been made is important and that secondary use of data might be of a different nature. Omitting details from the interview transcripts weaken the data quality and affects potential re-analysis of the material. Transparency may be strengthened by indicating where text is removed. We recommend that the researchers review the request for omitting text carefully and expand on what is omitted where necessary.

The time and context of qualitative interview data may also be relevant, so that issues that are considered sensitive may change over time. Qualitative interview data may thus be released at a later date. On the other hand, data may also become more sensitive with time so that researchers’ knowledge of the context and ethical training is essential for evaluating what is the correct approach (de Koning et al., 2019). Un-sharing published data is difficult, caution from the researchers side is therefore essential to maintain participants trust and willingness to participate in research.

How research participants experience sharing their data is important. The vulnerability participants felt when reading their own transcripts is relevant for personal privacy and integrity. Making participants “feel stupid” is a negative consequence, which, according to general research ethical norms should be avoided. In this study participants were resourceful adults and experts on research data sharing, we therefore considered the study to be conducted in an ethical and responsible way. In contexts including vulnerable participants we would not recommend the reviewing of complete transcripts as a strategy to share data openly, neither would we recommend it for transcripts where potential sensitive issues are investigated.

Some participants in our study emphasize the workload of reading and deciding on what to share in the transcripts. The literature on member-checking also address the presumption that participants have time and capacity to read through the transcribed text (Carlson, 2014). To reduce the workload and exposure transcribing with complete sentences is one option. An alternative is to write extensive summaries of each interview for participants to verify and share as open data, while the complete transcripts remain closed.

Qualitative interview data have the qualities of observational data and are unique and irreproducible and thus valuable data to keep (Borgman, 2015). Their potential future value include historical research and longitudinal studies documenting changes in societies. The general hesitance multiple participants express towards data sharing illustrate that the ideal “as open as possible and as closed as necessary” in the context of qualitative interview data is not easily fulfilled, but require options for restricted access sharing. Because how and what data are used matters to research participants (Hardy et al., 2016; Shah et al., 2021), we call for broader exploration of qualitative data sharing with predefined purposes. Involving research participants in a dialogue on how to share data require extra work from both researchers and participants, but may be of great value to the research community as well as society, in general. Within archival studies, shared stewardship is used as a concept to describe involvement and dialogue with the population from who the material originates (First Archivist Circle, 2007). Applying this concept to research data management can contribute to the acknowledgement of the participants as stakeholder. Shared stewardship would call for dialogue with and involvement of participants in research, and would help researchers arrive at the right approach to privacy in each project. We therefore recommend further studies on shared stewardship and sharing of human subjects data which includes the view of research participants.

For sharing qualitative human subjects data, it is necessary for research data services to provide guidance for researchers on how to balance sharing of data with respect for the participants. While clear and explicit consent for data sharing makes open sharing of human subjects’ research data possible (The Research Council of Norway, 2021), each case will require individual assessments of what is ethical.

CONCLUSION

Identification and self-image are two different aspects of research participants’ privacy. Identification often receives more attention but protecting the participants’ self-image is equally or possibly more important to research participants. Our findings show how anonymisation can be impossible to achieve in interview transcripts, without losing value. Anonymising participants is particularly difficult when conducting qualitative research within a small community (Haugen & Skilbrei, 2021). Rather, protection of participants’ privacy can be achieved through protection of their self-image. This corresponds with the fundamental ethical guidelines for research to respect the people who participate in research, and further that “researchers shall seek to ensure that their activities produce good consequences and that any adverse consequences are within the limits of acceptability” (The Norwegian National Research Ethics Committees, 2014).
The exposure participants felt when reading their own transcripts is an important addition to the debate of personal privacy from a research data management perspective, leading to the question of whether there can be too much sharing and too much transparency? We argue that transparency and dialogue with the participants is important both for privacy protection and research quality. However, dialogue involves listening to the participants’ wishes and adapting to their requests. Shared stewardship is a concept from archive sciences embodying the participants’ rights and interest in their own material, and ensuring shared stewardship is relevant to research data sharing. The research data sharing community could by learning from indigenous communities by using shared stewardship to empower the data subjects.

De-identification and plain language consent forms are better strategies for protecting privacy than anonymisation, which is increasingly difficult to achieve. Protection of self-image and “good consequence” (The Norwegian National Research Ethics Committees, 2014) according to general research ethical guidelines, are important perspectives in research data sharing. However, open data sharing exposes human subjects to further risks as their data is available to all members of society, for whom ethical norms of the research community may not apply. Therefore, data sharing services should address the sharing of human subjects’ data with care, and set their own ideals of openness aside when necessary. By sharing experiences gained in the sharing of qualitative human subjects’ research data, we wish to illustrate how there is not a one-size-fits-all solution for privacy protection, but rather a need for a respectful and reflective dialogue.

ACKNOWLEDGMENTS
We wish to thank the participants of the study for their time, commitment, and valuable contributions.

ABSTRACT
The welding industry in the U.S. faces a serious shortage of skilled welders. The goal of this paper is to explore welding instructors’ attitudes toward applications of Augmented Reality (AR) and Virtual Reality (VR) as well as artificial intelligence (AI) in welding training. Such approaches could allow future welders to acquire welding skills faster and in a safer work environment. Also, the welding industry could attract a more diverse group of workers. This paper builds on previous literature and studies researching the use of AR, VR, and AI in welding and in other comparable industries. The paper reports findings from interviews with eight welding instructors at a community college to obtain insights regarding how they believe AR, VR, and AI could be used in welding training. The paper provides implications for using AR, VR, and AI to attract and retain the next generation of welders.

INTRODUCTION
One of the challenges to revitalizing the manufacturing sector in the U.S. is that the U.S. is currently experiencing a serious shortage of welders (Akundi et al., 2022; American Welding Society, 2021; Chan et al., 2022; Ipsita et al., 2022). Welding plays a vital economic and societal role, as it is critical for constructing buildings, manufacturing vehicles, and transmitting energy (Kah & Martikainen, 2012). Welding is costly (Akundi et al., 2022; Chakradhar et al., 2022; Chan et al., 2022), dangerous, and presents potential health risks (Hill et al., 2022). Also, there are not enough new welders to replace welders who retire or leave the profession (U.S. Bureau of Labor Statistics, 2022).

Increasing automation threatens to eliminate jobs for skilled trade workers (Holm & Lorenz, 2022). Concerns about new technologies replacing skilled trade workers go back to the 18th Century (Pynchon, 2014). In the 1930s, John Maynard Keynes popularized the term “technological unemployment”, meaning “unemployment due to our discovery of means of economizing the use of labor outrunning the pace at which we can find new uses of labor” (Keynes, 1930, p. 3). This term is now often used to describe the effects of automation on the job market (Holm & Lorenz, 2022; Howcroft & Taylor, 2022). Many economists and technologists believe that the prospect that artificial intelligence (AI) might displace human workers could have serious consequences for the socio-economic landscape (Deranty & Corbin, 2022; Tyson & Zysman, 2022).

The aim of our research is to suggest ways to recruit and retain more welders with the help of AI instead of replacing them through automation. Through our study, we would like to explore how AI could potentially improve welding training to augment welding skills, and make the training more attractive, safer, and accessible. We seek to add to the current literature on the use of AI in welding by combining previous research with insights from welding instructors to propose a more comprehensive approach. By including the voices of welding instructors (most of them welders with extensive experience), we hope to provide deeper insights into the field and find possible solutions that incorporate the needs of current and future welders. A combination of different approaches and the use of AI may allow a larger group of potential workers to enter the welding trade (including those with accessibility issues), and would also make them more likely to remain on the job due to a safer and healthier work environment and improved job satisfaction (Hill et al., 2022).

In this paper, we first review the relevant literatures on welding training, the use of Augmented Reality (AR) and Virtual Reality (VR) in welding training, and the use of AI in welding training. Next, we share the results of an exploratory interview study conducted with eight welding instructors at a local community college in 2022. We found that the welding instructors we interviewed were overall very open to using AI technology in welding training, and they had many creative ideas about ways AI could assist students in their training. Through our study, we explore welding teaching methods currently used by the instructors, how AR and VR could be used in training in general and in welding training in particular, and how other AI technology could be helpful for welding training. Based on the findings of this research, we suggest that further research should explore how AI can be leveraged to improve training for welders and perhaps other skilled trade workers.
**BACKGROUND**

**Welding training**

Welding is part of the vocational training at community colleges. Welding training is a combination of teaching practical welding skills and soft skills. Good technical skills are the basis for being a good welder. Good technical skills alone, however, do not guarantee success. For example, Gauthier (2020) convened a focus group of ten engineering and manufacturing employers to understand what skills and knowledge they view as critical for community college welding programs to impart. Based on the perspectives provided by employers, Gauthier concludes that social competency is viewed as critical by employers, including communication, teamwork, and ethics. Similarly, Hora et al. (2018) mention welding as an example of where an apprenticeship could provide useful additional teaching including “how professional welders talk with clients, interact with other welders, and troubleshoot welding problems” (p. 35) and thus learning ways of “reasoning, communicating, interacting, and being” (p. 35). These examples demonstrate the need for skills outside the technical welding skills. As welding apprenticeships are not common in the United States, vocational training often includes these kinds of soft skills in the teaching at vocational teaching facilities like a community college.

**AR/VR training**

There is a large body of literature on how AR and VR can improve vocational training in general, including industries like assembly, automobile, engineering, or maintenance (see Chiang et al., 2022). Several previous studies have, in particular, researched how welding training could be advanced through the introduction of AR or VR (Agrawal & Pillai, 2020; Akundi et al., 2022; Chan et al., 2022; Devagiri et al., 2022; Ipsita et al., 2022; Papakostas et al., 2022). The detailed and very technical literature review of Devagiri et al. (2022) describes different AR techniques and models to demonstrate how AR and VR could be used in various industries. Chen et al. (2022) conducted an extensive literature review of papers related to AR and VR used in vocational welding training of welders to improve psychomotor skills. Their article is a valuable resource to provide instructors with AR/VR tool choices and methods used in vocational training and hopefully improve future interventions using AR and VR. As the authors illustrated, this might serve as a model for other industries.

Experiments with AR/VR in welding demonstrate that approaches using AR and/or VR can improve welding results (Akundi et al., 2022, Shankhwar et al., 2022, Stone et al., 2011). A welding study conducted with high school students in India demonstrated that the introduction of AR in welding training was beneficial (Agrawal & Pillai, 2020). As a result of the project, high school students learned through a mobile AR welding application in a safe and accessible way. Following testing in three schools, experts found the results promising. In another experimental study, researchers administered skills tests to two groups of Mechanical Engineering students after they completed training in either traditional welding or a combination of AR and traditional welding (Akundi et al., 2022). One group received three training sessions with traditional welding methods; the other group received three sessions with AR and then traditional welding. The class with AR welding training achieved significantly better results; the training was less costly, and the enrollment for classes increased because of the safer environment due to the use of the technology. The improved results could, however, also be due to the group receiving additional instruction time by adding AR training to the traditional training. Papakostas et al. (2022) conducted a separate study, exploring user acceptance of an AR welding simulator by using the Technology Acceptance Model (TAM), which questioned 200 trainees about their use of the AR welding simulator system for engineers. The trainees thought the AR training was useful. In another extensive study, the researchers designed a VR learning system, the VRWeldLearner, to provide an easy to use and low-cost way “to transfer skills to the real-world environment” (Ipsita et al., 2022, p.2). This user study that included 24 participants demonstrated that the approach was successful. The researchers recommend using the system for welding novices and in non-welding environments to “promote interest and welding education for choosing the trade as a career choice” (Ipsita et al., 2022, p. 19).

A particularly creative study experimented with a robotic arm that gave haptic force feedback to the participant while welding in a virtual environment (Ye et al., 2023). This approach was unique but may have additional cost implications, as robotic arms are quite expensive at present. A pilot study in Japan involved the development of a wearable device that provided tactile feedback through vibration. This information supplemented the virtual training (Chikai et al., 2020). However, the study involved to only three participants and is thus very limited. To date, the program has not been tested with a larger population.

Another study involving agriculture students led to less promising results (Wells & Miller, 2020). Participants completed a training session with either traditional welding or a mix of traditional and AR welding training. Results showed there were no significant differences between welds produced with AR training and without, but the authors of the study believed that their study should be replicated (Wells & Miller, 2020, p. 166). Over 70% of the participants had previous welding experience and the training session was less than one hour which might have diminished the validity of the results.
AI Technology
Besides AR/VR applications, Deranty and Corbin (2022) found that the use of AI through sensors could decrease training time, increase the quality of work, and make the job environment safer and more accessible (see Deranty & Corbin, 2022). Sensor technology exists in various forms (Wang et al., 2020). Few studies, however, have researched how such technologies can improve welding training and/or address health and safety as well as accessibility concerns associated with welding.

Quality of Work
One of the studies that researched how AI may improve the quality of welding training through sensors is a study where sensors measured wrist-hand motion skills and showed that focusing on these movements can improve the quality of the welds and could be used in welding training with success (Pribadi & Shinoda, 2022). An interesting new study uses welding tools augmented with a multisensory user interface. These tools use extended reality in welding training to provide real-time feedback without needing the constant supervision of a welding instructor. The study produced successful results, although it pointed out that so far it has only limited applications (Lee et al., 2023).

Safety and Health
Hill et al. (2022) demonstrate that different dangers in trades such as welding can cause occupational hazards and lead to health problems which should be addressed. Currently, only a few studies have directly researched the use of AI to address safety and health concerns in the welding industry and welding training. Studies that do examine how AI could address safety and health issues, often relate to other professional areas, such as construction and rarely reference training (Nath et al., 2017, Yang et al., 2020).

Yang et al. (2020) suggested that the construction industry could ensure proper protection of workers through the use of AI by applying sensors to Personal Protective Equipment (PPE) and connecting these sensors to hand tools (Yang et al., 2020). The paper introduces an automated PPE-tool-checking system prototype that would send signals like sound and vibration to the tool and also apply an emergency stop. Such an approach warrants further review and could apply to welding training.

Nath et al. (2017) demonstrated how the construction industry can use wearable mobile sensors to identify ergonomic risks for construction workers (Nath et al., 2017). They do not connect their proposed method to the use of smart hand tools (tools that use embedded sensors, edge intelligence, and the Internet of Things). The ideas presented in the article, however, could serve as an inspiration to develop smart hand tools that can alert workers to ergonomic risks, and thus, try to mitigate work-related injuries. As Nath et al. suggest, this can serve as a raw model for other occupations that are prone to work-related ergonomic risks because of awkward positions. Using a welding torch can also cause specific strains and injuries, so this approach could also benefit welders.

Ideas from other industries include predicting tool wear, e.g. of a milling tool (He et al., 2022) or a cutting tool (Korkmaz et al., 2022), to notice when a tool is not in good condition and could potentially hurt the user of the tool. This would increase workplace safety and make the working environment less hazardous which also could benefit welders and welding students.

Accessibility
Accessibility in this context refers to physical limitations. Sight, hearing, tremors, or other physical limitations may prevent people from entering the welding trade.

Accessibility is an important but understudied topic. Some literature explores how AI can make work more accessible. Abril-Jimenez et al. (2022) address how smart technology can support the needs of ageing workers. While the article focuses on office workers and AI tools that promote a healthy living style, we can apply its lessons. The article explicitly mentions training and skills acquisition as a benefit of technology for ageing workers. The most relevant study for our research is a study of how accessibility can be improved for deaf welders (Hill et al., 2023).

Our review of the literature revealed an opportunity for additional studies regarding accessibility barriers such as sight, hearing, or other physical limitations, and how AI may address these barriers to increase accessibility.

RESEARCH QUESTIONS
The three main research questions guided our research on instructors’ perspectives on welding training and the role that computing technologies can play in welding training.

- What are the goals of welding training from the perspective of welding instructors?
- What are welding instructors’ perspectives on using AR/VR technology in welding training?
- What are welding instructors’ perspectives on using AI technology in welding training?
METHODS
This paper reports findings from a larger interdisciplinary project focusing on designing smart hand tools that can benefit skilled workers such as welders. That project is in turn one of the core research projects for Good Systems, a UT Grand Challenge (Fleischmann, 2020; Fleischmann et al., 2019), an interdisciplinary project at the University of Texas at Austin focusing on defining, building, and evaluating ethical human-AI partnerships. Researchers from the School of Information, the LBJ School of Public Affairs, the Walker Department of Mechanical Engineering, and the Chandra Family Department of Electrical and Computer Engineering are collaborating to develop solutions that can leverage AI to enhance skilled trades by upskilling workers and improving their work conditions instead of replacing them. This study about welding training builds on prior studies by our team focusing on engineering students who build race cars (Hill et al., 2022) and deaf welders (Hill et al., 2023), but reports findings from a new research site, a local community college with a welding program. It has been approved by the Institutional Review Board of the University of Texas at Austin.

The first two authors attended multiple class meetings for three introductory courses at two teaching locations of a local community college in the fall of 2022. Class instructors taught Tungsten Inert Gas welding (TIG), Metal Inert Gas welding (MIG), and Shielded Metal Arc welding, also called Stick welding. The first two authors conducted in-field observation and took field notes during periods of instruction as well as during the students’ work time at their individual workstations. The field observations helped researchers to create focused interview questions and to gain a deeper understanding of welding processes. After the initial observations, the same researchers interviewed eight welding instructors from the community college (about half of the welding faculty) over a period of two months (November to December 2022). The interview questions (see Table 1), developed by all four authors, focused on instruction, technology use in welding in general, and how smart hand tools (including VR/AR applications) could be applied.

| Background Information | 1. How long have you been a welder?  
2. Do you specialize in a specific kind of welding? If so, which kind?  
3. How long have you been teaching people how to weld?  
4. How long have you been an instructor at [local community college]?  
5. Why is being a welding instructor important to you? |
|-----------------------------------------------|
| Instruction Insights | 6. Can you tell me about your process for teaching students how to weld?  
7. What do you enjoy about teaching students how to weld?  
8. What challenges do you face when teaching students how to weld? |
| Critical Incident: Best Experience | 9. Can you tell me about one of your best experiences in teaching students to weld?  
10. What were you trying to teach them?  
11. Why was this a good experience?  
12. Did this experience impact your teaching moving forward? |
| Critical Incident: Difficult Experience | 13. Can you tell me about a time when it was difficult to teach students how to weld?  
14. What were you trying to teach them?  
15. Why was it challenging to teach this to them?  
16. Did you make any changes to your teaching process as a result?  
17. Has this changed during the period that you have been teaching? |
| Critical Incident: Use of Technology | 18. Can you think of a specific technology or resource you’ve used in the past that made it easier to teach students how to weld? |
| Teaching Goals | 19. What do you want students to learn in your classes?  
20. Are you preparing students to obtain certifications, and if so, which ones?  
21. What careers are you preparing students for?  
22. Can you give some examples of jobs that your students got after graduation from the welding program? |
| Perspectives on Smart Hand Tools/VR and AR | 23. In this project, we are designing smart hand tools, or hand tools with embedded sensors and intelligence that will be able to provide feedback to the user. Can you imagine how this “smart hand tool” could be used and applied?  
24. What functionalities would you want this smart hand tool to have?  
25. Are there any particular welding techniques or aspects of the welding training process where a smart hand tool would be particularly useful? |
26. Are there other technologies you could imagine incorporating into a smart hand tool?
27. Do you think it would be helpful to display any information in the welding helmet? What kinds of information could be displayed and when would it be useful?
28. Do you think virtual reality should have any role in the welding training process?

Wrap-up

29. Is there anything I haven’t asked about that you think would be helpful to know?
30. Do you have any questions for us?

Table 1. Interview questions

The interviewed welding instructors have very different welding and teaching experiences from each other as can be seen in Table 2. Most of the instructors are generalists and teach multiple welding techniques and facets of welding.

Table 2: Welding and teaching experience of instructors

The first two authors conducted the interviews via Zoom Audio, with each interview lasting 25-55 minutes. They recorded the interviews through Zoom and transcribed them using an online transcription service (Rev.com). They coded the resulting transcriptions using tables in Word and individually created a first round of codes and themes. These two authors then compared their results and discussed the codes and themes with the third and fourth authors. Following this discussion, the first two authors merged codes and created new common themes. The basis for the coding process was reflective thematic analysis (Braun & Clarke, 2012), which allows for capturing the various lived experiences of the welding instructors to gain insights through common patterns and themes. The researchers continuously adjusted the codes over time and also discussed them with other researchers to refine them.

Throughout the following sections, to protect the identities of our participating welding instructors, we refer to our eight participants using the anonymized labels P1-P8.

FINDINGS

Three themes emerged from the interviews: “Goals of Welding Training,” “Instructors’ Perspectives on Using AR/VR Technology in Welding Training,” and “Instructors’ Perspectives on Using AI Technology in Welding Training.” This section provides an overview of the finding related to each theme, as well as example quotes.

Goals of Welding Training

The instructors aim to prepare the next generation of welders and are proud of their profession. P3 pointed out the importance “to hone their skills so that they can become a professional welder”. Several instructors share a deep appreciation of the welding profession (“honorable trade”, “lost art” – both P3, “trades are vital” - P2). They enjoy sharing their knowledge, enjoy seeing confidence build up in the students (P7) and hope to see them “gainfully employed as a welder” (P3). They aim to give back to the community to “help the future welders ... be more knowledgeable about their job” (P8). P6 expressed that he aims to “get the next generation better, ... trying to raise the standard of what welding is in this area” (P6).

The field observations and the interviews showed that welding requires significant practice and patience. Most instructors therefore concentrate on hands-on experience and try to provide individualized training to teach practical skills. As one instructor put it “Welders don’t live in theory, welders live in results” (P6). The majority divides the time into 20% theory/demonstrations and 80% hands-on practice; some instructors provide slightly more theory instruction (30%/70%). Teaching is often focused on the individual student. P4 noted that they “tend to lecture each student individually based on their needs and what they’re struggling with” and that “Welding is one of those things where it is not a one size fits everybody”. P3 pointed out “There is not one approach to presenting ... information to students”, that it is a “multifaceted approach” and that “students process the information differently”. Another one remarked that “The challenge is getting through, getting into their brain and figuring out each student individually … each person is gonna learn slightly different” (P6).

Instructors mentioned the diminishing interest in the trades and the lack of skills of students. Many students lose interest after a few classes because they do not seem to advance quickly enough and lack the patience demanded of the job. They mentioned that there is a “huge lack of people with qualified skills” (P6). One instructor pointed out that 10-15 years ago, the students were “more sincere about the direction they were going” (P3). Another explained
that some of the students, especially following the Covid-19 Pandemic “don't like going through that process of being not good at first”, “don't like the discouragement” and thus “they'll drop it quicker than they've ever done before” (P8). It is mentioned that “there can be a lot of frustration with the initial learning curve of just the hand-eye coordination elements that are required with welding” (P2). Another remarked that “developing those muscle memory, hand-eye coordination skills, ... can be difficult” (P2). As one instructor put it, another contributing factor is that some students have “never touched any tool in their life” (P1), which is dissimilar to some of the instructors’ own personal experience (P4). Instructors point out that students can feel intimidated by tools that feel foreign to them (P1). It is remarked that understanding welding “takes work and practice” (P8). Another instructor noticed a “huge lack of people with qualified skills” once he got into industry (P6).

The instructors’ insights show that the steep learning curve and the need for good hand-eye coordination can be frustrating for students who would prefer quicker success. They also reveal that attracting and retaining students has become more difficult over time.

Instructors additionally stressed the need for teaching the students soft skills to be compatible in the job market. The instructors emphasized that they aim to teach the students more than just direct welding skills. The instructors mentioned people skills (P3), soft skills (P1 and P7), teaching them to be an “honorable person” (P3), showing them how to have a good work ethic (P4), to be a “well-rounded individual” (P7), or to think logically about things (P1). This underlines that, for most of the welding instructors, their teaching goes beyond teaching technical skills.

**Instructors’ Perspectives on Using AR/VR Technology in Welding Training**

In interviewing the welding instructors, we were surprised to discover that the community college owns an expensive virtual welder, but the instructors at the community college are not actively using it for training purposes. Welding instructors believed that the virtual welder was not useful for their instructions and mentioned that it is mostly used for public demonstrations. They provided different explanations for why it is not useful, such as a lack of accuracy or it not being realistic enough, pointing out that “it’s not that accurate” or “it’s like a video game, but it’s not realistic” (P1). One instructor voiced the opinion that one needs to have the real-life experience because “you gotta get in and feel the fire” (P3). Another one confirmed this by saying “there’s a lot of value in ... actually doing welding where you’re getting burned and there’s sparks falling on you” (P1). P8 pointed out the “we’re not wanting to do that [virtual reality] as a replacement of actual welding. It is not quite the same”. In contrast, most of the instructors we interviewed reacted positively to the idea that a virtual welder could be useful in training. Even though they sometimes had not used virtual welding tools themselves, they considered that it “might be a good teaching resource” (P2). Even the instructor who did find it inaccurate and unrealistic (P1, see above) found that they “could see it being used as a teaching aid” (P1). The novelty of AI applications or interfaces was also seen as an advantage. One instructor remarked that especially the “newer generation people who are more apt to look at something that has more ... AI or more of an interface where they can play with it and they can understand it that way, I think it’d be a great application in that essence” (P4). One instructor would like to see virtual reality in “the three entry level classes, intro to Stick, intro to TIG, intro to MIG ... It would get them in the goldilocks zone faster, and then they could build their higher-level skills on top of that once they have honed it faster through that spot.” (P6). Instructor P6 saw benefits in using VR in intro level classes also for safety reasons, “Cause they wouldn’t beburn themselves right off the bat. They have less debris flying around. They’re not breathing fumes from toxic materials or any of that other stuff to get the skills” (P6). They stressed, however, the limited usefulness of VR by pointing out that “virtual reality absolutely has its place”, but that “they’re not gonna get past a certain point” (P6). Another instructor pointed out that they have been an advocate for developing welding games for children, “just getting kids interested in very young ages about trades. ... I could see how games and automation could do that. They have had hand and hand coordination. They can’t play the games that they’re playing without it. Now, it’s just turning that eye and hand coordination into a marketable skill.” (P8).

Another beneficial aspect of AR/VR welding was cost. P4 mentioned that “... we’ve watched metal prices and just steel, quadruple” and added “If they would be start working through that in virtual reality setting and then to go to the real thing would be a cost saving aspect” (P4).

Several instructors identified YouTube videos as an effective tool to teach welding (P3, P4, P5, P6). These videos are not directly related to AR/VR but this shows that the instructors are open to more digital approaches.

Thus, the instructors’ perspectives on AR/VR are quite mixed. They had access to an expensive VR simulator but chose not to use it. In contrast, they did use less expensive technologies such as YouTube videos in their instruction. Overall, the instructors felt that AR/VR could potentially serve as a useful tool but not as a complete substitute for traditional training.
Instructors’ Perspectives on Using AI Technology in Welding Training

In general, the instructors reacted favorably to introducing new technology. One mentioned that though they “haven’t really leaned on many technologies” they are “open to them” (P2). Instructors saw AI technology as potentially beneficial in different ways such as letting students achieve higher quality in less time, addressing safety and health concerns, and making the profession more accessible.

Reaching a higher quality of welds quicker can improve the welding training overall. The instructors had many ideas on how welding tools could be improved with sensors and alerts to achieve higher quality welds.

Most welding instructors mentioned measurements of travel speed, angle and arc length (P1, P2) as useful measurements and feedback, suggesting that either a visual interface in the hood or audio signals (P2, P4, P7) could mark the acceptable values, or as one instructor put it “the goldilocks zone” (P6). P1 remarked “having things in the sensor that tells the welder when they’ve gone out of their parameters of their welding specification would be useful when they’ve exceeded... their ... travel speed or gone below travel speed”. Displays in the welding helmet could include color indications, like green or red signals (P2), or as one instructor suggested, with sliding bar graphs (P6).

One instructor, however, saw the danger of this potentially as being too distracting (P3). P4 stressed how the quality control by having measure available right away could be useful, “Being able to have something where you could put on the glove and you could be able to touch certain areas of a part and have that pull up and dimensions real quick depending on ... what kind of technology you could stuff into a smart tool, that might be a thing” (P4). Another instructor mentioned that it would be useful to learn how much pressure to apply (P5). P1 suggests how this could be integrated into the teaching process. “I think that the welder would have to tell the teaching aid... how long the weld is and what size of weld that they’re supposed to make”. P6 added that “Even the say entry level kind of person, if you can get them on board with it telling ’em shorten your arc length or it’s telling ’em you need to move faster and it’s building up what they’re seeing and it’s a heads-up display ... If they have a heads-up display that’s telling ’em that in real time, it will absolutely make them a better welder, and it’ll make ’em a better welder faster.” (P2).

The interviews revealed that sensors alerting welders to the right parameters either visually or through audio cues are seen as a useful addition to improve welding students’ outputs as long as they are not distracting the welder.

The welding instructors also saw benefits of AI application with regard to safety and health. P7 pointed out that “welding and metal working is inherently dangerous”. Our field observation showed that the welders’ workplaces are hazardous with sparks emerging from the welding tool. There was also a danger of eye damage as a result of staring directly into the flame unprotected. P3 found it important that their students would “be able to complete the job in a safe ... environment.” Another instructor addressed health concerns, in particular health risks related to poor air quality and noise in the workspace and thought technology might be able to help. They suggested building an air quality sensor into the welding helmet to alert the welder if the air quality became poor or having an alert when the decibels reached a certain threshold indicating that the welder should wear earplugs (P7). They also addressed safety issues regarding the risk of blinding, suggesting that it would be beneficial to have sensors that could tell what shade is needed while welding (P7). AI could help provide advanced safety features to achieve the suggested goals.

Additionally, instructors were interested in using AI to overcome accessibility barriers. We define accessibility in this context as a state of overcoming barriers for people with physical limitations. Instructors pointed out that many welders who are currently having a difficult time entering the trade have specific physical limitations. One instructor made us aware of the difficulties faced by welders with tremors. “If you have motor issues especially the ones you see with ADD, ADHD, or kids that tremor. ... It is very hard to work past some of the physical issues.” (P8). Two instructors mentioned age (P1, P8) and having age-related visual impairment. “We had an older student who has maybe some visual things going” (P1). “With my older welders, I think it’s just seeing in general”. (P8). One instructor specifically remarked that “we’re all physically build different from tall to lean, to short and stocky, to tall ... and a lot of those things, believe it or not, they can hinder you or they can help you significantly in this field. ... some people don’t have that mechanical aptitude, some people can’t see that well, some people can’t hear that good. Some have physical limitations. ...” (P5), pointing out that “if we can create some technology to level that field, then that’d be awesome.” (P5).

Thus, the interviews revealed that there are issues related to accessibility. If the problem of accessibility could be addressed with AI-enhancements this could potentially decrease barriers, increase inclusivity, and encourage more people to enter the field of welding.

DISCUSSION

The literature reflects many of the points raised by the instructors, though to varying degrees and not always related to welding. There are specific studies addressing welding issues and general studies of how to use AI for hand tools in other parts of the industry that can be applied equally for welding. The topic most discussed in the literature about welding and new technology is welding and AR/VR. Much less can be found about AI-enhanced welding tools.
addressing safety and health issues or accessibility. Most of the studies we found focused on a single approach (either AR/VR solutions, or sensors) without providing a holistic view of welding training.

**Welding training goals**

An important aspect we learned regarding welding instruction is that welding training goes beyond just teaching practical welding skills, as the interviews with the instructors emphasized. The instructors stressed that they do not want to just teach their students technical skills, but to also provide students with a well-rounded education that includes soft skills to make them competitive on the job market. Similarly, literature examining vocational training confirms that soft skills are important for skilled workers (Hora et al., 2018). Employers find social competency an important skill in addition to technical skills (Gauthier, 2020).

Additionally, the instructors mentioned that students acquire skills in many different ways and that there is not just one path to success. Some explained how they varied their teaching styles to accommodate the individual needs of students. This emphasizes the need for teaching that does not provide one solution for all but allows for different approaches. Individualized teaching enables instructors to adapt to different situations and needs.

Hence, the best way to incorporate advanced technology in welding training could be to combine AR/VR teaching with traditional teaching by a person to allow individualization. Training should also ensure that the traditional welding teaching provides soft skills instruction as well as hard skills to prepare the students for their future workplace. We therefore recommend integrating AI in welding training without neglecting traditional teaching methods, in particular regarding soft skills, provided by welding instructors.

**AR/VR training**

Our interview findings align in many ways with the prior literature. Overall, the studies in the welding context as well as our interviews with the welding instructors seem to confirm that AR/VR training could be beneficial for vocational training (Akundi et al., 2022, Stone et al., 2011).

Even though we discovered that the instructors were hesitant to use VR technology, they also stated that these interventions could be a useful addition to the training. This might appear as a contradiction at first but can be explained. The instructors interviewed for our study saw a benefit of using AR or VR as an additional learning tool, but they also want to stress that nothing replaces reality.

Based on the instructors’ perspectives, we conclude that it might be best to introduce AR/VR training early in a student’s schooling, preferably in secondary education, or as a complement to traditional training methods. Our research suggests that AR/VR training cannot and should not replace traditional welding training, and that more advanced students who excel at AR/VR training should move to the real welding environment. The most beneficial use of AR/VR seems to be at the entry phase.

It is important to note that the VR welding machine that was available but not used at the training location was a high-priced machine. Our initial exploration supports the creation of low-cost and mobile solutions that may be easily used by each student. This supports previous studies (Agrawal & Pillai, 2020). Such solutions improve the affordability of AR/VR techniques and may make it financially available to a broader audience.

As the interviews with the welding instructors have shown, the instructors believe that AR/VR solutions can only help with teaching up to a certain point. They stress how virtual or augmented realities cannot replace a working environment with sparks, flames, and sound. The interviewed instructors, however, all had practically no experience with applying AR/VR methods in their teaching and were discussing potential use.

Further studies should examine to what extent and in what ways AR/VR technology could best be integrated into welding teaching. Several of the prior studies examining the use of AR/VR did not conduct long-term observations or experiments and covered very specific circumstances. One study examined mechanical engineering students (Akundi et al., 2022), another high school students in India (Agrawal & Pillai, 2020), and a third one engineers (Papakostas et al., 2022). Conducting additional research and longer experiments with various demographic groups may provide a more complete picture of how an integration of these technologies would be most beneficial.

**AI Technology in Welding training**

The interviewed instructors were open to adding AI to hand tools to improve welding quality and address other occurring issues. The interviews with the instructors confirmed the danger and health hazards of the welding industry as well as the problem of accessibility, and they were excited about AI’s potential application to make welding safer and more accessible in addition to providing higher quality instruction.

Our literature review showed that there is not much research on how to improve welding tools with AI. However, we found multiple studies relating to other industries like the construction industry (Nath et al., 2017, Yang et al., 2020), that we can apply to welding. Many of the studies relating to other industries address issues the welding
instructors mentioned in the interviews, like using sensors to indicate key measures for high quality welds (Pribadi & Shinoda, 2022), or sensors that make welders aware of dangerous working conditions (He et al., 2022, Korkmaz et al., 2022). Such ideas could be implemented into the welding training to make the welding training safer and allow students to achieve higher quality results quicker. This approach would hopefully attract and retain more students.

The application of AI to accessibility is important yet understudied. We recommend that researchers consider exploring how AI can improve accessibility.

LIMITATIONS AND FUTURE RESEARCH
Our study is an exploratory study and thus limited. The current interview study interviewed instructors at just one community college in one city. Different locations and environments could lead to different results. More interviews and surveys in varying places could also provide more and better insights. It would be worth studying whether various demographic backgrounds related to gender, race/ethnicity, socio-economic backgrounds, location, and previous experiences/exposure to technology would lead to different results. These aspects could potentially have an influence on the successful introduction of AI and AR/VR technologies. Conducting interviews with a wider range of instructors at a wider range of community colleges nationwide or even worldwide could provide a more complete picture.

The study is also limited in that researchers only conducted interviews with instructors and not with students or employers. In addition to gaining insights into how instructors feel about welding training, it would be useful to complement these insights with information gathered from welding students as well as companies employing welding students after they graduate. Combining different perspectives would allow for a more complete picture of how AI could support future welding training. As a next step, our project will explore students’ perceptions, attitudes and beliefs about welding and the use of technology and particularly smart hand tools in welding. In the future, the team will conduct interviews with students from the same welding program to complement the information gained from the instructors. Through this future study we aim to add the perspective of welding students to our research on improving welding instruction.

Another limitation is that the instructors we interviewed do not have experience using AI in their teaching. In future studies, it could be insightful to conduct user research on integrating AI-enhanced teaching techniques into the welding training and then interview instructors and other stakeholders about the experience.

CONCLUSION
Based on these preliminary results, we suggest that one promising approach would be to enhance traditional welding training with a multi-layered and holistic approach. For younger students and beginning students, we suggest using low-cost AR training tools to provide a safer, less costly, and easy to use tool. Such a tool can introduce beginning welders or students who are not sure yet whether they would want to become a welder to the welding trade. It can offer an easily accessible tool to test a student’s welding technique. The same tool could also help to accompany traditional training for beginning welders to provide more practice opportunities. A novice welder could even practice at home without any welding equipment with such tools.

In real-world training, we find sensor-based welding tools to be potentially highly effective to train welding students quicker and safer. Further research to discover ways in which these sensors could provide information, would be useful. The current research discusses examples worth reviewing but mostly lacks an in-depth analysis or testing of such approaches. More work is needed to explore how such approaches could assist beginning welders.

Equally, we suggest the need for further research related to ways accessibility issues could be addressed by the welding profession. There is a need for further research that can explore how additional AI technology could help accommodate students with a broader range of skills and abilities, which could both expand and broaden participation in the welding profession.

Our study indicates that the use of new technology, combined with traditional welding instruction, may yield benefits. While AR/VR training can be useful, the responses in our study support that hands-on guidance through experienced instructors in the real world with heat, dust, and all other elements of the daily welding work environment should not be replaced or substantially reduced. As the instructors in our study pointed out, there is no substitute for the real experience. There are also many ways students acquire the required skills. Personal instruction accompanied with soft skills instruction may best to prepare future welders for their careers. AI has the potential to support the creation of an inclusive and effective environment for welding training when it is designed to align with the needs and values of welding instructors and students.

The information we collected through our literature review and qualitative research shows how the use of technology in vocational training, in particular AI/AR and VR, has the potential to make a difference in the real
world. Implementing Smart Technology in in addition to traditional training can attract and retain skilled trade workers and thus benefit industries like welding who currently face serious labor shortages.

ACKNOWLEDGMENTS

We would like to thank all of our research participants for generously sharing their time and expertise. We would also like to thank the reviewers for their helpful feedback on an earlier version of this paper. This work was supported by funding from Good Systems, a research grand challenge at the University of Texas at Austin; Microsoft Research; and The MITRE Corporation.

ABSTRACT
The primary goal of this paper is to explore users' desires for digitized historical image collections, examining their desires based on different use purposes and information interaction activities. In addition, we investigate the image attributes that users wish to search from the collection. To accomplish this, we conducted 21 qualitative interviews with active users of a digitized historical photograph archive. Our findings suggest that users' desires relate to three contexts: tools, collection, and socio-organizational issues. Moreover, our results indicate that users require support for various information interaction activities, not just searching. We found that users' desires vary based on their specific use purposes, and that users prioritize conceptual access points that can already mostly be generated through automated annotation methods. Ultimately, this study contributes to a better understanding of users' real-life image needs and offers implications for improving access to digital image collections.

KEYWORDS
Cultural heritage collections, digital archives, digital images, image archives, information behavior, information interaction, information needs, user studies

INTRODUCTION
The digitization of cultural heritage collections has significantly improved user access to materials, including historical image archives that have been increasingly converted into digital format. However, little is known about information behaviors related to the use of historical images, as existing research on digital collections has focused primarily on textual materials (Chassanoff, 2018). This lack of research has resulted in a limited understanding of how digitized historical image collections are utilized, how well they meet user needs, and what users expect from these collections. Previous studies have revealed that image searching can be challenging due to its reliance on textual descriptions (Roberts, 2001). Yet, creating textual descriptions is resource consuming and challenging as the meaning of an image always depends on the viewer. Thus, the same image may have varying interpretations.

For designing sustainable digital collections, it is important to understand the real-world information behaviors related to the use of the collections (Borgman, 2003). Otherwise, some crucial aspects of work practices that shape the use could get ignored. It has been argued that research on this area lacks qualitative approaches to truly understand the image needs and uses (Cho et al., 2022; Matusiak, 2017). Providing contents openly online is not enough if they cannot be found, accessed, interoperated, and reused, as suggested by the FAIR principles (Wilkinson, et al. 2016).

The aim of this paper is to provide new knowledge about the desires users with different use purposes have for digitized image collection and the relations of their desires to different information interaction activities. Further, we investigate the attributes users wish to search from the collection. Our research questions are:

RQ1: What do users desire from a digitized historical image archive?
RQ2: In which information interaction activities do the desires relate to?
RQ3: How do desires vary across different use purposes?
RQ4: Which image attributes users want to search from the collection?

Our analysis is based on 21 qualitative interviews with experienced users of digitized image collection containing approximately 160,000 historical images from the early 20th century. This collection was not originally intended for public use but for providing illustration for the propaganda organization during the Second World War in Finland. After its digitation in 2013, the collection has been a popular source of image data for, e.g., genealogists, other hobbyists, journalists, and history researchers.

The paper is structured as follows; First, we provide background about digitized image archives and their uses and possibilities. Next, we present our research setting, including data collection and analyses. After this, we present our findings followed by discussion and conclusions.

BACKGROUND
Image Archives and Their Uses
Digitized image archives are collections of, for example, photographs originally produced in analog format and later digitized. Historical photographs are cultural heritage documenting our past visually. They are used for various
purposes and by various stakeholders including scholars, educators, the public, and commercial actors. However, there is a lack of understanding of how and why digitized image archives are used as most of the earlier studies focusing on cultural heritage collections study textual materials as image use has been mainly studied from the perspective of searching.

Information interactions arise out of nothing, but rather are triggered by either leisure or work-related tasks (Järvelin et al., 2015; Toms, 2011; Vakkari, 2001). Earlier studies have analyzed the image use for illustration and information (e.g., McCay-Peet & Toms, 2009). Digital archives are popular sources for collecting images to illustrate publications, social media posts, etc. One example of the use of images for information is their use as research data. Indeed, images are important primary sources for historical research, and images are used for verification, documentation, or corroboration (Chassanoff, 2018). Beaudoin (2014) studied image use among archaeologists, architects, art historians, and artists. She discovered that images were used for various purposes such as for knowledge creation, conceptual modelling, inspiration, cognitive recall, critical thinking, communication, emotion, engagement, marketing, proof, social connection, translation, and trust. In her study, the image use varied between user groups; those in archaeology and art history used images most often for knowledge creation for their lecture presentations and for research and publications as those in architecture and art used images for research and design creation.

Various studies show that although images are visual data they are mostly searched textually (e.g. Matusiak, 2017, 2006; Ménard & Khashman, 2014). Kumpulainen and Ruotsalainen (2022) studied the search tactics used for finding images from digital wartime photograph archive in the context of serious leisure. Based on a survey data they showed that keyword searching was the main tactic used along with filtering and browsing. Further, the study by Late, Ruotsalainen, and Kumpulainen (2023) indicates that keyword searching alone is not often an appropriate search tactic but must be accompanied by other tactics such as filtering and browsing. However, using the image archives comes with many difficulties in terms of discoverability, copyright, size, and quality (Beaudoin & Brady, 2011). Late, Ruotsalainen and Kumpulainen (2023) show that the incompleteness of metadata is the major barrier to the use of a digital image archive. Beyond historical images, literature review by Cho et al. (2022) revealed obstacles in image searching that were related to semantic problems, content-based issues, technical limitations, issues of aboutness, inclusivity issues, search skills, and cognitive overload.

Image Needs and Supporting Them

There is much to be improved in providing images for the users. According to Chassanoff (2018) historians desire original descriptive information, such as captions, keywords, subject headings, original medium, and the size of the images. More generally, earlier studies have outlined key requirements for digital libraries to be easy to learn and to use and deliver reliable search results (Kani-Zabihi, Ghinea & Chen, 2006; Kimani et al., 2009). Matusiak’s (2019) study focusing on community archives shows that users value developed interfaces, high quality of objects, good metadata, contextual information, and wide coverage. The design of the systems, as well as the terminology used, should be clear, consistent, and easy to understand (Thong, Hong, Tam, 2002). Other studies have shown that users desire, for example, visual-based interfaces to support faceted searching (Suominen, Viljanen & Hyvönen, 2007) of which a map-based search is only an example (McIntosh & Bainbridge, 2011).

Previous research has also examined the specific attributes that users search from the images. For example, McCay-Peet and Toms (2009) investigated the types of image attributes used by historians and journalists when selecting images for their work. They analyzed both conceptual and descriptive image attributes, drawing on earlier frameworks developed by Jörgensen (1998), Laine-Hernandez and Westman (2006), and Shatford (1986). Participants ranked attributes such as person/animal/object and event/action (conceptual), as well as viewer response and visual elements (descriptive), as the most important. Interestingly, no significant differences were found in attribute types based on whether the images were being used for information or illustration purposes. The authors recommend further research to explore the relationship between image needs and work tasks, with the aim of developing image retrieval systems that truly meet the needs of users.

User tagging and content-based image retrieval (CBIR) have revolutionized the way accessing and interacting with images, by providing cost-effective and high-density access points. CBIR techniques have already enabled recognition of people, objects, events, and landscapes in images, while newer methods can even identify photographic arrangements, such as distance between objects or camera or orientation, and recognize main characters. Other possibilities are, for example, reverse image search or finding similar images to those already found. (Seker, et al. 2021) However, Beaudoin’s (2016) study revealed that while CBIR was found useful by users interested in formal characteristics like color, shape, composition, and texture, it did not benefit users interested in known-items, themes, or locations. Archaeologists and art historians in the study preferred text-based retrieval of images over CBIR methods, underscoring the importance of user studies in determining real-life user needs.
Moreover, limited resources may prevent cultural heritage collections from adopting novel methods for digital archives.

**RESEARCH SETTING**

**Case Image Archive**

This study explores the use of a digital collection comprising approximately 160,000 unique photographs captured during the Second World War in Finland, between 1939 and 1945. The collection, provided by the Finnish Defence Forces, is available in print as well as digital format and features images depicting various aspects of the war. These include life on the home front, events and operations at the front, the war industry, leisure time at the front, damages caused by bombings, and the evacuation of Finnish Karelia. Most of the photographs were taken by wartime Information Company photographers and were used for wartime propaganda. While the majority of the photographs are in black and white, a small number of color photographs and videos are also included. The collection was published online in 2013 and is openly accessible to users in both Finnish and English via http://sa-kuva.fi/.

The digital images can be accessed using an online search interface that includes keyword search, advanced search with Boolean operators, and browsing options. Users can also filter the images based on predefined stages of the war (Winter War, Continuation War, Lapland War), specific date information, and color images and videos. The search results display 15 thumbnail images per page, and users can click on a thumbnail to view a larger image, access related metadata, and download the image. Users can also submit additional information about the image to the archive at this stage. Guidelines, terms of use, and a description of the archive are provided.

Textual metadata, created by photographers during wartime, forms the basis of the search. This metadata includes the name of the photographer, location, and subject or event depicted in the image. However, due to the chaotic wartime conditions, metadata is partly incomplete, and some photographers were unable to provide detailed descriptions. The metadata may also contain spelling errors and mistakes regarding the date and location. The metadata has not been edited or proofread and is primarily in Finnish, with some in Swedish.

**Data Collection**

The data for this study was obtained through semi-structured interviews conducted with 21 active users having experience over several years of the digital collection. The participants were selected to represent a range of roles (as presented in Table 1), including researchers (using images for research purposes), amateurs (using images for serious leisure activities such as genealogy and scale model building), journalists/writers (using images for illustration), and information specialists (searching images for their clients and for museum collections). The interviewees were selected through a combination of contacts provided by the research team and outreach to organizations known to use the archive. Each interviewee was also asked if they knew of anyone else (colleagues, etc.) who would be suitable for the interview. The goal was to gather a diverse range of experiences with the collection.

The interviews were conducted online using the conference tool Zoom during November 2021 and April 2022 until saturation was reached. All interviews were video recorded, and the video files were fully transcribed for analysis purposes. The average length of each interview was 37 minutes, resulting in a total of 12 hours and 48 minutes of audio data. Prior to the data collection, informed consents were obtained from all interviewees.

**Table 1. Profile of the participants.**

During the interviews, participants were asked a series of questions from the interview guide including background information such as their status, research field, and age. To explore their experiences with the image collection, a variation of the critical incident technique (Flanagan, 1954) was employed, where interviewees were asked to describe how they had used the collection, including searching, selecting, and saving images from the archive for one specific task. In addition, each interviewee was asked “What would be the perfect world searching engine like? What could you do with it?” to collect participants’ desires for the system. However, interviews did not necessarily follow the order of the questions in the guide, but the guide was used as a checklist to keep track of the interview. Also, before the interview, the interviewees were told shortly about automatic annotation methods to give them information about possibilities for developing the system. This, however, guided the thinking of the interviewees toward desires for the search engine and possibilities of automatic annotation. Also, it should be noted that participants could express their desires for the system at any point during the interview.
Data Analyses
To analyze the interview data, a combination of Atlas.ti software, Microsoft Excel, and SPSS were used. Firstly, the interview transcripts were uploaded into Atlas.ti and read through multiple times to identify instances where participants expressed their desires for the image collection. By using the concept of desire, we refer to the expectations, aspirations and needs that users have regarding their utilization of the collection. A total of 271 instances were identified from the data. Quotations expressing these desires were then extracted and entered into an Excel spreadsheet for further analysis.

For providing an answer to RQ1 (What do users desire from a digitized historical image archive?), desires were categorized according to their context utilizing categories provided by Kumpulainen and Late (2022). In this specific study, the contexts of tools, collection, and socio-organizational issues were utilized. Next, the subcategories (total of 19) for the contexts were coded data-driven. Regarding the RQ2 (In which information interaction activities do the desires relate?), the information interaction activities provided by Järvelin et al. (2015) were coded for identifying the activity the desire was related to. The theoretical model by Järvelin et al. (2015) is based on the idea of task-based information interaction (TBII) to assess how the information interactions contribute to the goals of task performance. Activities of searching/selecting, working with items, and synthesizing/reporting were applied in the coding. Searching and selecting activities were combined since an earlier study had shown these activities to be overlapping (Late & Kumpulainen, 2022). As all desires were not related to any specific activity an additional category “general” was formed. The context of desires and information activities the desires were related to were cross-tabulated and the Fisher’s exact test was run with SPSS software to test for statistical independence between the categorical variables.

To address RQ3 (How do desires vary across different use purposes?), we analyzed the primary use purpose of the digital collection for each interviewee. We identified the primary use purpose from the interviewees’ descriptions, following the categorization used by Fidel (1997) and McCay-Peet & Toms (2009) for information (users who looked for specific information from the images, such as research data) and for illustration (users who looked for images for illustrating publications). We also included an additional category, information mediating, for those who looked for images for their clients or for building collections. However, it is important to note that these were the users' primary use types. Users looking for images primarily for information could also use the images later for illustration, and users looking for images for illustration may have gained new information from the images and metadata that affected their searching behavior. To study the differences between different uses of the collection (RQ3), we cross-tabulated the context of desires with the primary use type. We used Fisher’s exact test with SPSS software to test the statistical independence between the categorical variables.

Finally, to providing an answer to RQ4 (Which image attributes do users want to search from the collection?) image attributes the users expressed they wanted to search from the collection were coded from the original data. Although we did not ask directly about image attribute needs during the interviews, participants expressed their needs while describing their research problems and image search habits, resulting in 173 expressions. The attributes were categorized either as conceptual (image of/about) or descriptive (image is) following the categorization used by McCay-Peet and Toms (2009). Attribute subtypes were formed data-driven but later standardized with subtypes used by McCay-Peet and Toms (2009) when possible. Illustrative quotes from the data were chosen and loosely translated from Finnish to English.

RESULTS
Desires
Interviewees’ desires for the digitized historical image collection were related to either the tools (N=174, 64.2%), the collection (N=82, 30.3%) or the socio-organizational issues (N=15, 5.5%). Most desires were related to searching/selecting activity (N=182, 67.2%), while desires supporting working with items (N=52, 19.2%) and synthesizing/reporting (N=13, 4.8%) activities were less common. A subset of desires that did not relate to any specific activity was classified as general (N=24, 8.9%). The results of Fisher’s exact test (p < .001) indicate a significant association between the context of desires and the activities they were associated with. Generally, desires related to tools were predominantly associated with searching/selecting activity. For desires related to the collection, over half were related to searching and selecting, while some were related to working with items activity. Socio-organizational desires were mostly associated with general issues and not tied to specific activities.

Users’ desires related to tools supporting searching/selecting (see Table 2) concerned most often possibilities for content-based recognition that could help them to identify various attributes they wanted to search from the collection.
I think I would benefit a lot from AI-based automatic character recognition that would identify dogs, other animals, people, etc. This would very likely show images that I have missed, and it would open up my research results and bring new points of view already in the search phase. At least it would make it faster. (P1, researcher)

Participants expressed a desire for more advanced search options, such as recommendation systems and map-based searches. Some also hoped for a system that would facilitate serendipitous discoveries by allowing them to stumble upon unintended images from the collection. Additionally, they sought an improved interface that would enable personalization, visualization of search results, and easy browsing. Researchers, in particular, desired various tools to aid them with working with items, such as the ability to further analyze outputs from the system, zoom in on images, and access analysis tools for their own collection retrieved from the system. For synthesizing and reporting users wished for functionalities that support image sharing.

Table 2. Desires in the context of tools according to information interaction activities. (N=174)

In the context of the collection (see Table 3) desires supporting searching/selecting were about improving and increasing the metadata, that users wanted to be curated and formalized. However, at the same time, they wanted to preserve the original captions within the images. Participants requested also clear guidelines and support for searching the contents and accessing all the images in the collection. This was related to the decisions to remove some images from the collection because of sensitive content. Regarding the working with items, participants expressed a need for high-quality digitization of the images, including capturing the backsides that could contain valuable supplementary information.

Definitely the backsides of the photos should be integrated before someone makes up that we have the photos digitized and that is enough. I haven’t even once made research without browsing the originals (P5, research)

In addition, participants expressed a desire to link contextual data, such as information about the events and individuals depicted in the images. Concerning synthesizing and reporting, participants emphasized the importance of trustworthy metadata, as they did not want to publish images with inaccurate information. Published images also needed to be of high quality and have clear licenses. Participants expressed a general desire to expand the collection beyond the wartime period and include images from other non-digitized collections.

Table 3. Desires in the context of the collection according to information interaction activities. (N=82)

Only a few desires were related to socio-organizational issues (Table 4). Researchers using the collection expressed a need for new quantitative research methods capable of handling large sets of historical images. Related to reporting activity participants hoped for ethical standards for publishing of the images. This was especially related to inexperienced users and their lack of information about the collection and its origins. General desires were about possibilities to correct and produce image metadata for the collection collectively. One participant also wished for more visibility for the collection.

> For many photos, there is specific information out there [that is not integrated into the collection]. Mostly about the vehicles, persons or places (P17, amateur)

Table 4. Desires in the socio-organizational context according to information interaction activities. (N=15)

**Differences Across Primary Use Purposes**

The study found that participants used the collection for various purposes, including finding images for information (N=12), illustration (N=6), or information mediating (N=3). The purpose of use was closely linked to the user's work role, with the majority of researchers and amateurs using the images for information (81.8% and 71%, respectively), while professional writers primarily used images for illustration purposes (100%). Information specialists mainly used the collection for information mediating (78.7%) or for information (21.3%).

In Table 5, the differences between participants using the collection for different purposes were examined in relation to the context of their desires (The results of the Fisher’s exact test (p = .033) indicate a significant association between the variables). Participants using images primarily for information or illustration purposes expressed more desires for tools as those using the collection for mediating information had more desires for the collection and socio-organizational issues.

Desired Image Attributes

Our analyses showed that users were intrigued by the prospect of automated content recognition for images. To delve deeper, we studied the attribute types and subtypes that users wanted to identify from the image collection. Our analysis included a total of 173 attribute expressions, many of them overlapping. Conceptual attributes, which refer to images about something, comprised the majority (77.5%) of the expressions, while descriptive attributes, which describe what the image is, accounted for the remaining 22.5%. Table 6 below displays the various attribute types and their corresponding subtypes, along with examples.

Table 6. Attribute types and subtypes expressed by the interviewees. (N=173)

The majority of conceptual attributes related to identifying specific persons, objects, or animals within the images. Users expressed a desire to search for images featuring humans, dogs, vehicles, buildings, and more. Additionally, attributes of persons and objects were frequently mentioned, with a particular emphasis on recognizing individual people.

In the ideal world, there would be a face or shape recognition system that would enable to identify the persons and search them (P3, information specialist)

Furthermore, users expressed a desire to search for images of specific troops, buildings, or brands. They were also interested in finding images based on characteristics such as gender, age, nationality, and role (such as children or soldiers), as well as images taken in certain locations or milieus, such as towns, forests, or indoor/outdoor settings. The ability to search for certain activities and events, such as battles, Christmas, or parties, was also highly desired. An interesting observation was the propaganda nature of the image collection, with users expressing a desire to determine whether the photographs were staged or based on real events. Additionally, participants expressed interest in images featuring expressions and emotions, such as people who appeared tired, serious, or happy, as well as images depicting temporal attributes, such as time of day or season.

I study the history of emotions and it would be interesting to see how for example gender and certain emotions are correlated in the photos. Or age for example. Or can we find the same facial expressions from men and women? (P15, researcher)
Regarding descriptive attributes, users expressed the most interest in descriptive information about the images, such as the date and name of the photographer. Some users were also intrigued by image composition, including factors such as the distance between people, their posture, and the number of objects or people in the image. Additionally, the direction of activity depicted in the image was important, particularly for those seeking images for use in illustrations.

*For example, searching soldiers skiing from left to right. For illustration, it is very important to get the direction right.* (P7, professional writer)

Moreover, participants expressed a desire to understand the external relation of the images, such as images belonging to the same photo series or those published in certain forums. Additionally, users expressed a need to identify the color and image type, as well as other visual elements present in the images.

Furthermore, we examined whether there were any significant differences in desired attribute types among users in different work roles or with different intended use purposes. However, no significant differences in desired attribute types were found. It is possible that there may be differences in subtypes, but due to the relatively small size of our data set, we were unable to conduct a thorough analysis on this front.

**DISCUSSION**

The objective of our study was to analyze users’ desires for digitized historical image archives, with a focus on the information interaction activities related to those desires and the intended purpose of image use. Additionally, we examined the image attributes that users sought to search from the collection. Our findings shed light on the contextual factors surrounding user desires and provide insight into the types of support that users require at various stages of their information interaction process. Ideally, image archives should offer a wide range of access points to their contents and provide comprehensive support to users throughout their entire information interaction process.

With respect to RQ1 (What do the users desire from a digitized historical image archive?), our analyses show that user desires were related to the contexts of tools, collection, and socio-organizational issues. We utilized the model by Kumpulainen and Late (2022) that was originally created for studying the context of barriers in information interaction. This model turned out to be useful also for recognizing the contexts of user desires. Desires connected with tools were the most frequent in our data, relating, for example, to the automatic annotation of the images, providing improved search options, and developing the interface. Interviewees were intrigued by the possibilities CBIR techniques can offer, such as automatic character recognition. This finding conflicted with the results by Beaudoin (2016) who argued that scholars in archaeology and art history were not interested in CBIR systems but wanted to rely on textual descriptions. However, it is likely that during the six years between the studies, technology has developed and users are more familiar with the supports AI can offer. Furthermore, the tasks behind the image use may also differ between the studies. In addition, as already shown in earlier studies users desire visual search systems such as map-based searching, as the location is an important attribute in images (Suominen, Välijänen & Hyvönen, 2007). Digital services should also support serendipity, which is important in historians’ research process (Martin & Quan-Haase, 2013). Desires related to the *collection* discussed, for example, improving the image metadata and the quality of digitization. Indeed, metadata of historical images has been shown to be a major barrier to image searching (Late et al., 2023). *Socio-organizational* desires were infrequently expressed in our data but brought out important views for the development. One of the issues was the need for new research methods in the historical domain using images as research data.

Regarding the second research question (In which information interaction activities do the desires relate to?) our analyses indicated the association between the context of desires and information interactions identified according to Järvelin et al. (2015). For example, desires for *tools* were typically related to *searching/selecting* activity as desires for the *collection* mixed between *searching/selecting* and *working with items* activities. *Socio-organizational* desires were mostly related to general issues, not associated with specific activities. According to our findings, most desires were related to *searching/selecting* activity. However, this is partly due to our data collection method as the interviewees were asked to describe their ideal world image search engine. However, the finding is not very surprising as information interactions with the collections become less frequent towards the end of the interaction process (Late & Kumpulainen, 2021). It is also obvious that users expect similar functionalities that are provided by commercial search engines such as Google. Thus, it may be disappointing for them to realize the shortcomings of cultural heritage collections that have limited budgets for their development. Despite the limitation in our data collection, some desires related to *working with items* and *synthesizing/reporting* activities were raised. For example, researchers desired outputs from the system to be further analyzed. As the majority of the earlier studies have focused on image searching, we argue that future studies should take the whole information interaction process into account to better understand the information behavior and user needs.
The third research question was about analyzing the desires across primary use purposes, namely for illustration, for information, and for information mediating. The results showed that user desires varied between those participants using the collection for information/illustration and information mediating. Also, earlier research has shown variation in image use according to the user’s task and profession (Beaudoin, 2014). These observations underline the importance of task-based research settings and confirm that the task behind the user behavior triggers what users want from the system. However, detecting the purpose of use might be challenging as in real-life users have various needs within a single task (Byström & Kumpulainen, 2022). Their use purpose may also change along the process and images that were originally searched, for example, for illustration may be used for information mediating and/or for information. Therefore, we analyzed participants’ primary purposes, and this limitation may decrease the reliability of the results.

Our last research question focused on the image attributes users want to search from the collection. The majority of the identified attributes were conceptual according to categorization by McCay-Peet and Toms (2009). However, we did not study the importance of the attribute types or their sub-types. Yet, it seems that the frequency of expressed attributes relates to their importance since three out of the four most frequent attribute subtypes were the most highly ranked attribute types also in the study by McCay-Peet and Toms (2009). When comparing the attribute subtypes with the categorization used by McCay-Peet and Toms (2009) we found two new subtypes: attributes of persons/objects (conceptual) and composition (descriptive). As McCay-Peet and Toms (2009), we did not find significant differences in attribute types according to the use purposes.

We used a qualitative interview method to collect critical incidents of digitized image archive use. However, the case system under the study (and its limitations) affects the realities and desires of the participants and we collected only ex post facto accounts of the users’ experiences. To fully understand the user desires beyond the service level there is a need for more realistic research settings, such as longitudinal ethnographic research to capture real-life information interactions beyond a single system. However, our results provide several practical implications for developing historical image archives. Users desire various tools to help them in using the system and utilizing the images. Although many of the tools are designed for supporting searching, it is vital to recognize that image searching is not only about locating the desired images from the collection, but they are used also as a method for analyzing the data. For the moment, our case image archive gives no means for analyzing one’s own subcollections collected from the system. Users conducting, for example, computational humanities research may want to collect multiple images at once and export outputs of the image metadata from the system. So far, all this needs to be done manually. However, there have been arguments that digital humanities researchers would benefit more from providing a palette-style selection of tools with proper interoperability functions, rather than direct pipelines for workflows (Koolen et al., 2020).

Automatic content recognition and annotation have much to offer for historical collections with limited metadata. Our findings provide concrete examples of the image attributes that users desire to search from the collection, most of which can be implemented if sufficient resources are allocated to the development of the archive. However, previous experiences have demonstrated that information needs in humanities research can be highly diverse, making it difficult to create a single unified metadata scheme. Therefore, users may require project-specific metadata (Lund et al., 2013). Another practical consideration for development is the digitization process; valuable information on the backsides of images should be included in digital surrogates. Moreover, users expressed a need to identify staged photographs in the collection and verify the authenticity of the images, which is particularly relevant for all visual contents.

Users’ desires included allowing collaborative metadata production (co-created metadata), as they experienced there is unused information about the images available. For now, users can send additional information to the archive, but the problem seems to be, that the archive has no resources to evaluate and integrate the information. Users are not able to annotate content directly. Behind the decision, there might be a fear of integrating false information into the system. One possibility for solving the problem is to provide co-created metadata as layers on top of the original metadata and let the users decide which to use. Developing cultural heritage collections requires both financial and intellectual resources to ensure the continuation of digital curation (Barbuti, 2018). Keeping on track with developments offered by commercial systems is not easy for publicly maintained services but it is crucial to provide access and support for various user groups and different uses of the collection.

CONCLUSION

While the majority of earlier studies have focused on image search practices or on the use of textual digitized cultural heritage data, this study aimed at providing a more holistic view of the desires users have for digitized historical image archives. We based our analysis on qualitative interviews with active users of an archive containing digitized photographs from the Second World War. Our findings shed light on the diverse desires that users have for image collections, as well as the information interaction activities related to these desires. Further, we analyzed the
image attributes users wanted to search from the collection. By doing this, we can better understand user needs and provide implications for improving access points to digital image collections from a human-centered perspective.

Among the key findings are that user desires for the collection are various and support is needed for different information interaction activities, not solely for searching. Our findings suggest that users' desires relate to three contexts: tools, collection, and socio-organizational issues. In particular, desires for tools were the most prevalent, including desires for automatic image annotation. On the image attribute level, our findings highlighted the need for conceptual attributes such as objects, object attributes, location, and events that were often absent from the original image metadata, which was not initially intended for current uses. However, automatic content recognition and annotation offer great potential for historical collections with limited metadata.

Our study raised several intriguing questions for future research, including the need to understand real-life information interactions with image data on a larger scale. While our study addressed some gaps in our knowledge by studying the use of one specific image archive, further research will be necessary to determine how image archives can develop their services to meet various user needs.

ABSTRACT
Mapping between different representations of similar data is a common challenge in digital humanities (DH). In practical DH collections, the ‘person’ is an essential and centric unit and other parts could link to the ‘person’ to form the knowledge base. However, there is still no general and useful person-oriented ontology in DH community. Many practical DH projects have developed their own ontologies by DH experts, but these ontologies are not interoperable. Therefore, it is important to explore existing biographical ontologies and develop a comprehensive person-oriented ontology for DH.

Using the metadata crosswalk method, we examined the ontologies provided for persons in three DH collections to analyze how they map onto standard ontologies such as FOAF (friend of a friend). This paper uncovers a significant and consistent gap between standard biographical ontologies and those used in practical DH collections, arriving at a set of heterogeneous problems, including different granularities of metadata. Consequently, we propose three key person-oriented ontological types of elements, drawing on this metadata crosswalk: basic biographical elements, relational elements, and explanatory elements (such as career, connected with role and time). This metadata crosswalk provides a foundation for future matching between person-oriented ontologies and facilitates semantic interoperability between DH collections.

Person-oriented ontology, Biographical ontology, Digital humanities, Metadata crosswalk

INTRODUCTION
With the increase in quantity and quality of DH collections, interoperability and aggregation among various DH collections could improve the validity and efficiency of DH systems and data. Several DH projects and standards have already aimed to achieve this goal in DH. Ontologies are a fundamental tool in achieving DH data interoperability and DH collection aggregation by using shared definitions and descriptions of metadata (Doerr, 2009; Usiskin, Walde, & Winter, 2019). In the DH field, many ontologies have been proposed for specific domains. Examples include the Committee for Documentation of the International Council of Museums Conceptual Reference Model (CIDOC CRM) for Cultural Heritage; Europeana Data Model (EDM) for Museums; Bibliographic Framework (BIBFRAME) and Library Reference Model (LRMoo) for Bibliographic data; and Dublin Core for all cultural data.

As DH continues to develop, ontologies are expected to represent not only the information about instance description but also the in-depth knowledge of content (Gracy, Zeng, & Skirvin, 2013). Relations and attributes about people are essential knowledge in DH. There are many small-scale DH projects that are based at universities. These projects have typically used proprietary metadata schemes (Salse, Guallar-Delgado, Jornet-Benito, Mateo Bretos, & Silvestre-Canut, 2022). They typically contain datasets about people: e.g., person-oriented collections or event-oriented collections which contain person as a critical element. A user-centered ontology design study of social studies teachers identified ‘people’ as a central category in cultural heritage domain ontology construction (M. C. Pattuelli, 2011b). However, existing ontologies in DH almost always focus on objects (e.g., documents or paintings) as their main items, and have less focus on representing individual people. For example, the cultural heritage object class in EDM, the event class in CIDOC CRM, and the work class in LRMoo.

Moreover, numerous difficult recognition problems with person-oriented data in DH collections need a concise and clear standard to solve them. For example, how to distinguish a person’s role in different events? A person’s roles in different events would change in different temporal and spatial situations, while this person might have an invariable professional role. For example, a professor could be the stage manager in one performing art event. In addition, different terminologies, different granularities, and different expressions in existing ontologies could also lead to some mismatching when linking persons in various DH collections. For example, the same person would have different name expressions in different languages, and even the words’ amount and space position showed various in different databases (McKay, Sanchez, & Parker, 2010).

86th Annual Meeting of the Association for Information Science & Technology | Oct. 27 – 31, 2023 | London, United Kingdom. Author(s) retain copyright, but ASIS&T receives an exclusive publication license.
Existing biographical ontologies and metadata standards that are commonly adopted could be a reasonable starting point to build a promising person-oriented ontology, but they are scattered in different dimensions which are hard to reuse directly. To some extent, the right person-oriented ontology could model these difficult representation and identification problems, but the DH field lacks a single, comprehensive and precise person-oriented ontology. In this case, we decided to utilize metadata schemas from practical people-centered DH collections to analyze and polish existing biographical ontologies, which is a semantic mapping method.

Metadata crosswalk is a method for analyzing how to transfer metadata from source metadata schemas to target metadata schemas, that contains semantic mapping and metadata conversion (Xu, Hess, & Akerman, 2018). In the digital library and cultural heritage fields, many studies have adopted metadata crosswalk as an essential metadata mapping method to accomplish interoperability among different conceptual models (Barroso, Hartmann, & Ribeiro, 2015; Gaitanou, Andreou, Sicilia, & Garoufallou, 2022; Gaitanou, Bountouri, & Gergatsoulis, 2012). But identification problems in practical data are still remained if only use lexical metadata crosswalk due to lack of enough semantic explanation (Ryan, Zhang, Durward, Matusiak, & Organisciak, 2020), such as the recognition problem about different people in the same names (Katsurai & Ohmukai, 2019). The properties about name could be unified by lexical metadata crosswalk, but people with same names need more semantic relations to be identified.

Mapping similar ontologies and their equivalent elements would increase the practical matching accuracy in DH collections, but it is complex to align all different aspects among multiple ontologies (Jett, Nurmikko-Fuller, Cole, Page, & Downie, 2016; Nurmikko-Fuller et al., 2015). Thus, we developed an ontology-based metadata crosswalk method to find a way to balance availability and accuracy. We use three research questions to analyze existing person-oriented ontologies:

What are the practical problems of existing DH biographical ontologies?
What are the key elements of person-oriented ontologies in DH collections?
How to construct a high-quality person-oriented ontology for DH?

This paper has five main sections to answer these three questions. Firstly, we review the person-oriented ontologies analysis literature. Secondly, we explain the metadata crosswalk method and data source in the methodology section. Thirdly, we present our results on the key elements and gaps about person-oriented ontologies that answer research question 1 and 2. Fourthly, we discuss the essential person-oriented ontology elements and construction methods to answer research question 3. Finally, we conclude our contribution in this paper and suggest avenues for future work.

LITERATURE REVIEW

Ontology, as a subset of taxonomy, goes beyond describing hierarchy and includes relationships between concepts within a specific domain. In the context of the Resource Description Framework (RDF), ontologies provide vocabularies for defining the basic elements of subject, predicate, and object. Building ontologies in DH could help reveal and organize heterogeneous and dynamic cultural information (Usiskin et al., 2019). In this section, we demonstrate the existing biographical ontologies in the DH field and review some related ontology analysis work.

Existing Biographical DH Ontologies

In this section, we illustrate existing biographical DH ontologies that are analyzed in this paper. These ontologies include:

Friend Of A Friend (FOAF): FOAF defines machine-readable webpages of people, organizations, and companies. Terms about people in FOAF can be divided into five categories: basic information, personal information, online accounts, projects and groups, documents and images. In FOAF, foaf:Person is the subclass of foaf:Agent, and foaf:Agent consists of person, group, and physical artifacts. In the DH domain, FOAF is reused frequently to present person-oriented relations because FOAF is simple and widespread enough to represent friends and acquaintance connections among people (C. Pattuelli, 2012).

A Vocabulary for Biographical Information (BIO vocabulary): The BIO vocabulary reused the term foaf:Person, and added event-related classes and properties to describe biographical information about the person. BIO lists detailed types of biographical events, such as Adoption, Divorce, and Retirement. There are three sorts of properties of the event: first, descriptive information of an event, such as date, place, and person’s position in this event; second, the person’s role in an event, such as a parent, partner, employer, or spectator; third, relations between different events, such as following the event and concurrent event. In the DH domain, event-centric ontology mapping is essential to semantic translate DH collections. CIDOC CRM is the most sophisticated ontology reused in many DH projects (Bruseker, Carboni, & Guillem, 2017).

An Extension of CIDOC CRM to the Biographical Domain (BIO CRM): BIO CRM extends CIDOC CRM by using a role-centric method to model a person’s life stories. BIO CRM defines three categories of properties to illustrate
all related elements around the person’s life. Firstly, attributes about a person’s characteristic information, such as name, birthtime, birthplace. BIO CRM defines gender, nationality, and occupation as the subclasses of bioc:Unary_Role. Secondly, relations between the person and other classes. Bio CRM has three key relations: family relations, achievements, and career roles (Leskinen, Tuominen, Heino, & Hyvönen, 2017). BIO CRM use bioc:Binary_Relationship_Role to define family relationships, social relationships, and group relationships. Thirdly, events include a person’s different roles happening in specific times and places. BIO CRM directly adopted the representation of the event in CIDOC CRM, using cidoc:P7_had_participant to link event and person, using cidoc:P4_has_time-span and cidoc:P7_took_place_at to describe place and time of the event separately.

The Person Part of Categories for the Description of Works of Art (CDWA): CDWA was built to describe and catalog different cultural works through a conceptual model. CDWA includes lots of different categories but identifies the minimum core elements. The person is a core type in CDWA, and core sub-elements of person are name, name source, display biography, birth date, death date, nationality, and life roles. In CDWA person-related elements, the relations among persons have also been illustrated, such as the date of life roles, the date, and place of person events, and the type and date of personal relationships. In DH, the most impressive crosswalk is the CDWA metadata crosswalk from the Getty research institute, which contains 14 metadata schemas about culture data, even though the CDWA metadata crosswalks include hierarchical lexical elements but not semantic metadata crosswalks with multiple relationships. Using CDWA as one of our target data is valuable for further interoperability with other ontologies in DH-related fields.

The Person Part of DBpedia ontology: DBpedia ontology is based on, and automatically extracted from Wikipedia person data. Therefore, it has detailed data classes about a person: e.g., different person roles, such as artist, writer, or architect. In DBpedia, even hair color can be defined as a property of a person. Although the DBpedia ontology lacks logical consistency and semantic hierarchy, many DH projects have used it to help identify persons in their own DH collections (C. Pattuelli & Rubinow, 2013).

Previous Work of Biographical DH Ontologies Analysis
Since the development of DH collections, more and more researchers have found potential value in person elements. Some person-oriented ontology mapping studies in DH have revealed the linkable properties of ‘person’. For example, Pattuelli (M. C. Pattuelli, 2011a) has done a systematic vocabulary mapping to investigate equivalent properties among nine person-related ontologies in DH, and divided these properties into their categories: personal information, online presence, as well as social and cognitive properties. Some other studies used the person as a linking trigger to enhance existing databases. DBpedia has an ample storage of person-related data and is updated dynamically by sourcing from Wikipedia. Thus, some studies used DBpedia as a tool to generate robust person datasets, such as a case study of Jazz Artist names (M. C. Pattuelli, 2012). In addition, FOAF is always used to present people connections, which could help explain complex relationships between people (C. Pattuelli, 2012). Langmead et al. (Langmead, Otis, Warren, Weingart, & Zilinski, 2016) tried to combine the six-degree network with FOAF ontology to improve the interoperability and flexibility of people relationship research in DH. Araújo (Araújo, 2016) has built an ontology of the person’s life story, especially for museum, by extending CIDOC CRM with DBpedia and FOAF. Due to some person-related concepts not being contained in CIDOC CRM, properties about gender, names, and person-image relations are extracted from FOAF; properties about religion, profession, education, and spouse are taken from DBpedia (Araújo, 2016).

There is some detailed and in-depth biographical ontology analysis in previous DH works. For example, Hyvönen’s research team has done some Actor ontology analysis about Finland Cultural Linked Data, such as BIO CRM, an event-based biographical ontology extent of CIDOC CRM (Tuominen, Hyvönen, & Leskinen, 2018), and created a data model for person names (Tamper, Leskinen, Tuominen, & Hyvönen, 2020). While this is a significant achievement, names in Finland are limited in form and content both linguistically and by the use of an approved name list for birth certificates. Hyvönen et al. (Hyvönen, Leskinen, Tamper, & Tuominen, 2018) made further contributions in 2018, when they built BIO CRM which clear distinguished attributes, relations, and events. They also presented three cases of applying BIO CRM. Their research demonstrated the validity of event-based biographical models, even though they still face problems when extracting relations from free texts and dealing with larger datasets.

Some studies focus on one aspect of person ontology. For example, GenderedCHContents ontology was built to represent specific elements of gendered concepts in cultural heritage field. It extended the Europeana Data Model by adding more classes and properties about gender (Kyvernitou & Bikakis, 2017). In 2020, Tamper et al. (Tamper et al., 2020) built a detailed data model, especially for the person’s names. In this person name ontology, they used NameUsage to describe some general characteristics of a name, such as a second name given due to marriage or a third name in a different language version. Furthermore, by practical cases analysis, the suffix of name, a person’s vocation, and genealogical research could also help name linking (Tamper et al., 2020).
Finally, there are some socio-technical problems for person metadata in practical DH collections, especially regarding name and gender. We found person’s name varies according to migration, pseudonyms, indigenous names, and legal name changes e.g., divorce or marriage (Sumner, Fensham, Cutter, & Mendelssohn, 2022). Compilers in different datasets would make different decisions about the display name (Cutter, Sumner, & Fensham, 2023). Gender transitions are also an important problem that causes ambiguity about names and creates a situation where the person concerned may not wish to have the two names linked (T. Wagner, 2022). These problems reflect the necessity of biographical ontology because the ontology uses not only name and gender to identify people but also multiple relations about people, such as family relations. Completing and improving person-oriented ontologies would help further understand and represent person metadata in realistic datasets.

METHODOLOGY

In this study, we use the metadata crosswalk as a key method to analyze person-oriented ontologies by mapping person-oriented metadata schemas in DH collections. Through our literature review, we selected BIO CRM, CDWA, FOAF, BIO vocabulary, and DBpedia ontologies as source material. In this section, we introduce the ontology-based metadata crosswalk method and three practical DH collections.

Ontology-Based Metadata Crosswalk

Metadata issue is a socio-technical problem which is always caused by tools, knowledge, organization, and people issues (Khoo & Hall, 2010). Metadata management is a crucial way to determine the granularity and structure of cultural databases. Metadata has different functions such as descriptive metadata, technical metadata, preservation metadata, rights metadata, structural metadata, and mark-up languages (Kartawihardja, Pee, & Zakaria, 2019).

Metadata crosswalk is a method to aggregate different metadata standards and better manage multisource cultural data. The metadata crosswalk is defined as mapping equivalent elements in different metadata schemas to allow systems to interoperable convert data (Chan & Zeng, 2006). Interoperability among multiple DH collections can be achieved through metadata crosswalks (Woodley, 2008). Metadata crosswalk development has different steps in previous works: verification of metadata actual use in datasets, identification of existing ontologies, and definition of metadata crosswalk (Barroso et al., 2015).

Several previous works have demonstrated DH scholars using the metadata crosswalk method to map one dataset’s metadata schema or one ontology to other ontologies. For example, Chen et al. used FRBRoo as a shared ontology to integrate different metadata in two museum collections, and a metadata crosswalk between Dublin Core and FRBRoo was done (Chen & Ke, 2013). Mapping traditional DH metadata standards such as Dublin Core and Encoded Archival Description to CIDOC CRM is also valuable in DH field (Doerr, 2000; Stasinopoulos et al., 2007). However, there is no systematic “ontology to ontology” metadata crosswalk research in DH. Instead, previous work focuses on converting lexical elements to ontology. Chen (Chen, 2015) has done an RDF-based metadata crosswalk to transfer equivalent elements in DC, EAD, and CDWA to RDF format (Chen, 2015). The Library of Congress has done a metadata crosswalk to transition MARC to BIBFRAME (Xu et al., 2018). With the development of semantic DH, there were lots of existing DH ontologies to enhance the semantic explanation in DH collections, and emerging more and more born RDF DH collections (Usiskin et al., 2019). It is complicated to use a traditional metadata crosswalk to satisfy the requirements of DH ontologies mapping (Khoo & Hall, 2010).

Ontologies often have hierarchical classes and different properties and relations among them, only using the “elements to elements” mapping method of metadata crosswalk would not represent the equivalent semantic relationships behind metadata elements.

Thus, we developed an ontology-based metadata crosswalk for the person-oriented ontologies analysis. Ontologies predominantly contain classes, object properties, and data properties. Compared with metadata, ontologies focus more on the content level by defining basic concepts and their relations, but without the description of the data resource (Stasinopoulos et al., 2007). This paper maps different person-related elements in practical DH collections to existing biographical DH ontologies. Our ontology-based metadata crosswalks focused on specific content and descriptive metadata that representing classes and relationships of different concepts related to people. Thus, we not map other administrative or structural metadata, including compliance and versioning data (Wu et al., 2022). In this paper, ontology-based metadata crosswalk construction was undertaken in four steps:

1. Metadata harvest and cleaning from DH collections (semi-automatically by developers)
2. Biographical ontologies selection through literature review
3. Mapping DH collections’ metadata schemas to biographical ontologies (manually by domain experts)
4. Identification and analysis of different elements in ontology-based metadata crosswalk
**Metadata in DH Collections**

Due to the complexity of different existing biographical ontologies, we decided to use practical DH collections to examine and analyze them. For this metadata crosswalk, we selected three mature DH collections with rich person-related properties. We now outline the person-related content of the three collections. We selected these three DH collections very carefully, not only person-oriented collections but also event-oriented collections with person as an important centric item. These collections vary in different levels of DH topics, but all contain rich metadata about a person. These three DH collections are partners of the projects Australian Cultural Data Engine (ACD-Engine) we participated in; thus, we can get access to the whole metadata scheme of them. One of the key purposes of ACD-Engine project is to aggregate different cultural ontologies to broaden the scale and accessibility of cultural collections.

The Australian Live Performance Database (AusStage) is a database about performing arts. As AusStage is an event-oriented database, the person element is represented as a contributor (to an event). AusStage mainly uses three relations to enrich an event, contributors to this event by functions, the event occurring venues, and organizations involved in this event. For each contributor, AusStage contains basic biographical information and related events, people, and organizations. Furthermore, events in AusStage identify their time and place.

Design & Art Australia Online (DAAO) is a biographical dataset of artists. For biographical data, it contains not only some basic metadata, such as name, gender, birth date, and birthplace, but also specific metadata about this dataset, such as detailed roles of different artists, active period, and indigenous information. DAAO also contains other relations about artists which could link to other data, such as the related people, groups, works, exhibitions, collections, and recognitions. For exhibitions, DAAO contains the date and place of the exhibitions.

Digital Archive of Queensland architecture (DAQA) is a biographical archive of the architecture containing architects, firms, projects, articles, and interviews. For architects, the primary biographical data is in the biography text. Relations of architects contain related architects, firms, and projects. Each relation in DAQA could be identified by its date and shown in the timeline of this architect. Project often has date and location information and associated firms and architects.

In conclusion, these three DH collections metadata schemas contain abundant person-related information, which can supply the required fundamental elements to construct an ontology-based metadata crosswalk. We report the details and outcomes of this metadata crosswalk in the result section.

**RESULTS**

This study adopts the ontology-based metadata crosswalk methodology. Specifically, we choose basic elements in ontology to express and indicate equivalent metadata mapping at the semantic level. An ontology comprises individuals, classes, and properties. Classes are interpreted as sets of individuals, and properties mean their relationships. Object properties represent relationships between individuals. Datatype properties link individuals to data values, such as an XML schema data value or an RDF literal. Conceptually, the ontology-based metadata crosswalk only consists of classes, object properties, and datatype properties.

The core class in this paper is ‘person’, even though some different names given to the class. In AusStage, the person is presented as a ‘contributor’ because of its focus on events, while some existing ontologies use ‘Agent’ for both persons and organizations. During constructing this ontology-based metadata crosswalk, we found that person-oriented elements could be divided into three types. Firstly, the basic elements of the person class are always represented as the datatype properties in ontology (see Figure 1). Secondly, relations between the person class and other classes are object properties in ontology (see Figure 2). Thirdly, explanatory elements about biographical data, which means there are further interpretive properties upon unitary properties about the person class (see Figure 3). In order to clarify ontologies from our DH collections and standard ontologies, the elements from standard ontologies all have capitalized initial letters.

We demonstrate the details of these three types in the following sections. Because we choose metadata in DH collections as the starting point to analyze existing ontologies in this metadata crosswalk, all conceptual elements in DH collections metadata schemas are presented in this crosswalk, while only elements that could be mapped onto these schemas in biographical ontologies are selected.

**Basic Elements**

In this paper, the basic elements of person-oriented ontologies are biographical datatype properties, which form the essential person description. In this metadata crosswalk, basic elements mainly contain person ID, name, gender, nationality, role (occupation), place, birth, death, language, biography text, and supplementary information. Through the investigation of different standards, we found extensive heterogeneity between schemas, such as different terms for the same property, different metadata granularity, and different data explanation orientations. Thus, it is necessary to compare and analyze the basic elements in various ontologies.
The name elements in practical DH collections are fine-grained. For example, DH collections often make a clear classification of first name and last name, and they often contain display name and alternative names metadata. However, existing biographical ontologies (other than FOAF) lack detailed concepts to represent different name formats. BIO CRM has an official name and alternative name classes but uses appellation to interpret details about the name component. BIO CRM simply uses strings to represent the main (‘display’) name and alternative names, which could simplify the compilation of large-scale datasets. Practical databases might not contain all alternative names of any given person. In contrast, dividing up name details will help identify more format changes about the same person, thus enhancing the accuracy of name matching in different datasets. More specifically, if one woman’s surname changes because of marriage and is presented as a new display name in another collection, this woman would be matched because the name details of both unmarried and married names are present.

Place elements consist of the current address of the person, which could contain country, state, or suburb. In existing ontologies, BIO and DBpedia only represent state, and BIO CRM uses E53_Place as the umbrella term to represent different geological information containing basic address metadata. CDWA and FOAF lack classes to represent biographical places.

In DH, birth and death are essential biographical elements and they are always represented as specific places and dates. Almost all existing biographical ontologies support the same details for this category except FOAF. In addition, CIDOC CRM represents birth and death as events, using P4_has_time-span and E52_Time-Span to represent date, uses P7_took_place_at and E53_Place to represent place. In order to be more concise, BIO CRM adopted birth_place and birth_time properties instead of the event-oriented representation in practical cases (Leskinen et al., 2017).

Two practical DH collections, DAAO and DAQA, contain biography as an element in their metadata schema. Biography often contains the details of a person’s life story and is represented in text format on the website of DH collections. Even though some known contents are represented in other elements, some working DH collections use unstructured biography text to enrich the basic information about a person. However, in existing biographical ontologies, only BIO vocabulary has a biography class.

In conclusion, for basic elements, different biographical ontologies have different priorities. Through our analysis, BIO CRM is the most completed biographical ontology, which is suitable to represent DH collections. However, we need to add more datatypetype properties to BIO CRM, such as biography and details of the name and place element.

Figure 1. Basic Elements of Person-Oriented Metadata Crosswalk
Relational Elements
In this study, relational elements refer to object properties that express different relationships between the person and other classes. Through our metadata crosswalk, we found that there are almost consistent relational elements in different DH collections. These three DH collections shared relational elements are relationships between a person with other **persons**, **organizations**, **events**, and **works**. These four elements are contained in almost all the existing biographical ontologies in this paper, even though they might have different terminologies. There are some different elements in the three DH collections that give more possibilities about relational elements in person-oriented ontologies.

Firstly, in AusStage and DAAO, the resource of **collection** is an essential relation of the person because DH collections often do not contain original data but rather knowledge processed by domain experts (Fenlon, 2019). The collection is also emphasized in Digital Library, and Dublin Core defines collection as the aggregation of physical or digital items (Wickett, Renear, & Furner, 2011). In existing biographical ontologies, only BIO CRM reused the E78_Curated_Holding to represent collections. However, the collection plays a vital role in practical DH collections exchanging and sharing, which means DH collections are more referential collections rather than directly holding data (Wickett et al., 2013). Identifying collection in biographical ontology would give more original information about the person from different data sources.

Secondly, in DAAO and DAQA, they contain the relationship between the person and their **recognitions**, which are only contained in DBpedia in existing biographical ontologies. The possible reasons are the applicability of different ontologies, and the award could be one sort of event. Though each ontology has an event class, representing and identifying events is difficult in practical DH collections construction because of their different project objectives. BIO CRM aims to use a person’s different role in the function of an event to link the relationship between person and event and further identify the specific event. Through the three DH collections, we found there might be some types of events that have common modes which need to be identified as a new element.

Thirdly, DAQA uses the **topic** as a relational element about the person element, while the topic is not shown as an independent property in existing biographical ontologies. However, the topic is always a key element in library collections catalogs (Zavalina, 2014). Similarly, the topic is important in DH collections website navigation, and the subject is an essential element in Dublin Core, a metadata standard frequently reused in DH collections.

Finally, the range and border of **production** property and **work** property need to be paid attention to. In existing ontologies, BIO CRM uses E12_Production to represent the activity event of creating a new item. E12_Production is represented as a temporal event rather than an object due to the event-oriented objective of CIDOC CRM. However, in practical DH collections, AusStage uses ‘work’ to represent inherent creation without temporal limits and uses ‘production’ to describe a different version of the work. DAQA uses more detailed production categories such as ‘project’ and ‘publication’, which mirror ‘pastProject’ and ‘document’ in FOAF. Thus, in existing biographical ontologies, it is necessary to add ‘work’ as an essential relational element and to use ‘production’ to represent temporal and special supplemented information about creative work. For example, the **work** is the original script, while a specific copy of this script is a **production** with version identification. Thus, production is a specific performance of that work in specific DH collections.

In conclusion, extracting more relational elements about persons in practical DH collections would extend person-related context in existing biographical ontologies. Constructing a comprehensive and transparent relations network about persons would help DH practitioners map multiple data sources and contents easier and give the end users a better browsing experience because they could gain related knowledge more smoothly.

![Figure 2. Relational Elements of Person-oriented Metadata Crosswalk](image-url)
Explanatory Elements

The final core elements category of this person-oriented metadata crosswalk is explanatory elements, and this is the final part of this crosswalk. In other words, some datatype properties or object properties of the person class need not be restricted in a single link but need more interpreted attributes to enrich their link. For example, we need more descriptions about person-related events. Not only the event itself should be represented, but also represent happening place and date of this event. In practical DH collections, we found it is not enough to represent basic elements and relational elements about person because information about people is changing according to different situations. Some existing DH ontologies have already found this issue and tried to represent these elements to solve it. For example, BIO CRM takes the event as a particular element involving participants in different roles and identifies them with space and time (Tuominen et al., 2018).

However, there are more elements, like events that need to have detailed explanatory information. We found four types of explanatory elements mentioned in our three DH collections and existing biographical ontologies.

Career is the most frequent explanatory element about the person class to represent person’s role in different period, which uses start date, end date and place to add more information. If one person has different occupations in different period and places, it would be easy to see the career changes.

Event is also an important explanatory element and event-related illustrated information consists of event type, function, date, and place. To be more specific, residences, training, and education explanatory elements are mentioned in two DH collections and DBpedia but hardly show detailed events items in other existing DH biographical ontologies. This phenomenon shows that there might be a gap between top-down ontologies and bottom-up database metadata schemas.

We found that the active period of a person appeared in DAAO and DAQA, expressed by a date range. However, it is hard to represent this explanatory element in existing ontologies because there is no straightforward concept in excising ontologies. It could be one kind of event or topic only consisting of temporal explanation.

Finally, the related person is an important explanatory element found in the schemas but not recorded in that way in any DH collection. CDWA applies relationship type and relationship data to represent a person’s relations with other people and groups. BIO CRM gives a specific classification of different social relationships around people to people. These sorts of person’s relationships show the power of ontology.

![Figure 3. Explanatory Elements of Person-Oriented Metadata Crosswalk](image)

DISCUSSION

In answer to RQ1, “What are the practical problems of existing biographical DH ontologies?” We found three key issues of existing biographical ontologies. Firstly, problems caused by heterogeneity between existing ontologies, such as different terms for the same class or property. Secondly, different granularity used to represent the same elements in different standards, especially regarding the time range of events. Thirdly, there is a gap between how
existing biographical DH ontologies and practical DH collections represent the same concepts, such as more detailed representation of creative production in DH collections than found in the schemas.

To answer RQ2, “What are the key elements of person-oriented ontologies in DH collections?” We now discuss the inadequate elements of biographical ontologies.

Even for basic elements, FOAF, BIO vocabulary, and DBpedia each lose important descriptive information about persons. BIO CRM and CDWA were created for cultural data description and comprehensively provide the basic elements about a person. The only consistent difference between basic elements in practical DH collections is the chosen granularity used to represent a person’s name. The fine granularity of name attributes in small-scale DH collections, combined with varying practices, shows that we need to consider how to align representations when working with multiple collections. Since using an ontology-based method provides more possibility of a person matching through diversity links, such as family relationships and specific events, we could consider distinguishing more details about names in person-oriented ontologies to help improve name management problems (McKay et al., 2010).

For relational elements, we found multiple relations among persons and other classes in practical DH collections. This shows that ‘person’ is often the pivotal class for linking knowledge in a collection. However, existing biographical ontologies lack the ability to capture those rich relationships found in the practical DH collections. CIDOC CRM is an event-centric ontology and consists of rich relations about cultural events. BIO CRM has extended that concept by adding comprehensive relational elements around the concept of person. Through the metadata schemas of practical collections, we found recognition could be one special relational element about a person (e.g., receiving an award). Though recognition could be one type of event, it is valuable to represent specific rewards or statuses of people. In addition, just one practical DH collection (DAQA) represented place as a relational element. In existing ontologies, only BIO CRM has the place as a relation of person. This argues against adding place as a relational element in a final model, because place could be contained in other properties. Practical DH collections always have their own small topics, and DAQA used the topic as a relational element. However, there is scant support for the topic in existing DH ontologies. From practical DH collections, we found the topic could be one potential relational element to include in a unifying model.

For explanatory elements, BIO CRM gives a particular explanation of role-centric modeling of events, which can use the person’s different roles in different events to enrich prosopography. Events are also characterized by place, time, and type. One of the practical DH collections also used this method to represent people-related events by using a person’s role as the event function. CDWA uses person’s relationships as an explanatory element that contains type and date of different relations among persons or groups. BIO CRM also targets a person’s social relationships as an important aspect of their life story. In practical DH collections, a person’s career plays an important role, which contains the start date, end date, and place. This type of explanatory elements also be emphasized in some existing biographical ontologies. However, the granularity of events differs in different standards, and there are more detailed events in practical DH collections. As the scope of the event is a complex problem in the DH field (Tuominen et al., 2018), identifying the type of event in person-oriented ontology construction is necessary.

In order to answer RQ3, “How can we construct a high-quality person-oriented ontology about DH?”, we found it would be easier to map complex elements in different ontologies by using the ontology-based metadata crosswalk. All content elements in the three DH collections could be identified as one of the three types in the metadata crosswalk. Thus, we summarize the three types of elements into a person-oriented ontology construction guide (see Figure 4). Through this guide, a DH developer could use the right box to identify datatype properties about a person, use the left box to link other relations, and use supplementary data properties to further enrich a person’s occupation, event, and relations with other people. This also provides a foundation for making different DH schemas interoperable and consolidates the current core concepts into a single guide.
CONCLUSION
In this paper, we contribute a comprehensive and systematic analysis of person-oriented ontologies using the metadata crosswalk method. In past ontology development and application research, the person class has not been a central element in DH ontology construction; collections such as digital libraries mainly focus on the description of documents and collections. Our paper offers a person-oriented ontology analysis which could lead to the person-centric ontology development.

In addition, we developed an ontology-based metadata crosswalk, which consists of basic elements, relational elements, and explanatory elements. We used a conceptual chart to give a summary of these elements. By using our ontology-based metadata crosswalk, DH researchers can easily identify different terms and expressions related to their person-oriented data. Through our analysis, DH researchers and practitioners would gain the prime and first steps for person-oriented ontology construction. Our analysis reduces the gap in current biographical ontological mapping by drawing on the evidence of real-world data formats. Furthermore, there are few previous studies using the ontology-based metadata crosswalk method. Our paper gives an instruction for using ontology property types to improve the semantic ability of the metadata crosswalk method.

Due to the complicated and time-consuming work of evaluating the metadata organization of large-scale DH collections, we have analyzed only three DH collections. More complex issues may be hidden in other DH collections’ data on people. The selected DH collections in this paper focus more on contemporary persons, while many existing DH ontologies focus on cultural heritage. However, today’s contemporary culture is tomorrow’s cultural heritage, so analyzing contemporary people-related metadata elements to improve DH ontologies is still of value for long-term planning. Contemporary culture also presents the issue of living people, who may have preferences and requirements about their representation, such as a requirement not to deadname (publicly describe a person using their former name) in the context of gender transition (T. L. Wagner, Marsh, & Curliss, 2023). Even though some socio-technical problems (such as the transition example noted above) are not addressed, the three key element types identified in this paper provide a concrete foundation towards constructing high-quality person-oriented ontologies that can be interlinked with other sources. In the future, we will choose the most capable and practicable existing biographical ontology to do a more specific analysis and improve on the results in this paper. Mapping data in practical DH collections to evaluate the viability of ontological data in real-time is also planned.

Negativity Bias During Information Seeking, Processing, and Sensemaking about a Policy Debate: An Eye-tracking Experiment

Liu, Yingtong | Peking University, China | yingtong66@stu.pku.edu.cn
Zhang, Jiajia | Peking University, China | 2000016657@stu.pku.edu.cn
Zhang, Pengyi | Peking University, China | pengyi@pku.edu.cn

ABSTRACT
Negativity bias is the tendency to pay more attention and give more weight to negative information than positive information. This study explored how negativity bias affects information search, processing, and sensemaking when reading news articles on controversial topics. We conducted an eye-tracking experiment with 43 participants who sought and read positive and negative articles about the three-child policy debate. We measured their eye movements, cognitive load, attitude change, and sensemaking outcomes. We found that: (1) negativity bias occurs in both information search and information processing, and the outcomes of sensemaking also tend to show negative changes; (2) reading positive articles increase cognitive load more than reading negative articles; (3) gender and prior attitude have an influence on negativity bias; (4) people use different cognitive strategies when making sense of positive and negative information. This paper contributes to a better understanding of negativity bias in information seeking, processing, and sensemaking, which can help design news systems that adapt to readers' needs, and suggests people view information objectively.

KEYWORDS
Negativity bias; Information seeking; Sensemaking; Attitude change; Three-child policy

INTRODUCTION
We live in an increasingly polarized world, where information is abundant and diverse, but also often negative. Negative news tends to dominate the media coverage of controversial topics, while positive news is seen as less newsworthy (Lengauer, Esser, & Berganza, 2012; Soroka, Fournier, & Nir, 2019). Moreover, audiences tend to be more attracted to and affected by negative information than positive information of equal importance. This phenomenon is known as negativity bias, which refers to negative events having a greater impact than positive events of objectively equal magnitude (Lazarus, 2021; Rozin & Royzman, 2001).

There are several explanations for negativity bias. A range of explanations concerns evolution and they generally follow from the same assumption: the observed asymmetries are a consequence of the asymmetry of positive and negative outcomes (Unkelbach, Alves, & Koch, 2020). The main idea of evolutionary explanations focuses on the threat (Lazarus, 2021; Unkelbach et al., 2020). It’s believed that due to natural selection, organisms that were more sensitive to negative stimuli had a greater chance of surviving threats, increasing their likelihood of passing their genes on to future generations (Baumeister, Bratslavsky, Finkenauer, & Vohs, 2001; Öhman & Mineka, 2001). What’s more, differential similarity (Unkelbach et al., 2020), perceptual salience (Skowronski & Carlston, 1989), and the like also have been proposed to explain negativity bias.

Negativity bias has been widely observed and studied in various fields such as psychology, economics, political science, and communication (Baumeister et al., 2001; Kenney & Kahn, 2002; Klein, 1991; Soroka & McAdams, 2015; Tversky & Kahneman, 1991). There are also studies from the perspective of information behavior. For example, negative information is more likely to be selected (Bachleda et al., 2020; Meffert, Chung, Joiner, Waks, & Garst, 2006), attracts more attention (Fiske, 1980; Pratto & John, 1991) and has a greater effect on cognition (Christenson & Glick, 2018; Grosskopf & Mondak, 1998). Many factors are related to negativity bias, such as gender (Bachleda et al., 2020; Soroka, Gidengil, Fournier, & NIR, 2016), age (Bachleda et al., 2020; Kisley, Wood, & Burrows, 2007), education, personality traits (Bachleda et al., 2020), prior attitude (Knobloch-Westerwick, Mothes, & Polavin, 2017; Li, Li, & Zhang, 2021; van der Meer & Hameleers, 2022). However, very little is known about negativity bias during the whole process of information seeking, processing and sensemaking, and the differences in cognitive processing when reading positive and negative articles.

In this paper, we explore how people seek, process, and make sense of negative information differently from positive information. We review various theoretical accounts and empirical evidence of negativity bias at different stages of information seeking. We also examine the cognitive processes involved in sensemaking when people encounter positive and negative articles. We choose the recently implemented three-child policy in China as the topic under investigation. The policy allows couples to have up to three children, aiming to address the challenges of...
an aging population and a low fertility rate. It has also sparked public controversy and debate since its announcement in May 2021. Our research questions are as follows:

**RQ1.** Does negativity bias occur during information seeking, information processing and sensemaking?

**RQ2.** How do demographic and prior attitude factors influence negativity bias?

**RQ3.** Do people show different cognitive patterns of attention when reading positive and negative articles?

This paper is organized as follows: We first review the literature on negativity bias and information seeking. Then we describe the experiment design, data collection and analysis methods. Finally, we present the findings, discuss their implications and limitations, and conclude the paper.

**LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT**

**Information Seeking, Information Processing and Sensemaking**

**Information seeking**

‘Information seeking behavior is the purposive seeking for information as a consequence of a need to satisfy some goal’ (Wilson, 2000). In the face of information overload, people have to allocate their cognitive resources rationally during information seeking, then biased information consumption occurs. Negative information is more likely to be selected (Bachleda et al., 2020; Meffert et al., 2006). Negativity bias may occur at different stages, including the perceptual process, judgment and retrieval of information from memory. Explanations for negativity bias vary at different stages (Kanouse, 1984). Furthermore, to cope with the uncertainty and threats attributable to news negativity, people tend to seek additional information, and highly negative news will induce more active information seeking behavior than weakly negative news (Park, 2015). Therefore, we propose the following hypotheses:

**H1a.** Negativity bias occurs during information seeking.

**H1a.1.** Participants select more negative articles than positive ones.

**H1a.2.** Participants select negative articles earlier than positive ones.

**H1a.3.** Participants read an individual negative article more often than a positive one.

**Information processing**

Previous research found that negativity bias often occurs during information processing and the negative advantage is reflected from attention, memory, person perception and impression formation, to attribution (Unkelbach et al., 2020). Negative information may be more "attention-grabbing" (Fiske, 1980; Pratto & John, 1991). For example, the experiment negative information interferes more strongly with the primary color naming task than positive information, which supports the attention advantage for negative information (Pratto & John, 1991); during a mock election campaign, voters seek more, spend more time reading, and recall more negative than positive information about political candidates (Meffert et al., 2006). Eye-tracking is a research method that uses an eye-tracker device to track the point of gaze or eye movement of an individual while executing a task (Borys & Plechawska-Wójcik, 2017). It has become a widely-used method to study the attention of a subject while performing various tasks (Kätsyri, Kinnunen, Kusumoto, Oittinen, & Ravaja, 2016; Möller, Baumgartner, Kühne, & Peter, 2021). Therefore, we propose the following hypotheses:

**H1b.** Negativity bias occurs during information processing.

**H1b.1.** Participants spend more time reading an individual negative article than a positive one.

**H1b.2.** The participants’ average fixation duration (AFD) is longer when reading negative articles than positive ones.

**H1b.3.** The participants’ average pupil diameter (APD) is larger when reading negative articles than positive ones.

**Sensemaking**

Sensemaking is the process of forming meaningful representations and utilizing them to develop comprehension, thereby enabling an individual to plan, make decisions, tackle problems, and generally act in an informed manner (Pirolli & Russell, 2011; Zhang & Soergel, 2019). The overall process of sensemaking can be seen as iterations of "information seeking–sensemaking" and may lead to three kinds of outcomes that update the conceptual structure: accretion, tuning or radical restructuring (Zhang & Soergel, 2014). Further, the update of conceptual structure related to a topic may result in a shift in attitude towards it.

Some literature concerning the Court showed the influence of negativity bias on the outcome of sensemaking. For example, disagreement with one or both edicts considerably reduced confidence in the Court, but agreement with both edicts brought only a marginal gain in confidence (Grosskopf & Mondak, 1998); disfavored decisions will have
larger negative effects on legitimacy than favored decisions will have positive effects (Christenson & Glick, 2018). It
seems that the effects of positive and negative information on cognition are asymmetric. One type of negativity
bias is negativity dominance, which means that the evaluations of combinations of negative and positive entities are
typically more negative than the algebraic sum of individual subjective valences (Rozin & Royzman, 2001).
Therefore, we propose the following hypothesis:

H1c. The participants’ attitudes towards the three-child policy change negatively.

Factors Related to Negativity Bias
There was a lot of work illustrating that negativity bias varies across individuals. Specifically, negativity bias was
found to correlate with characteristics such as gender (Bachleda et al., 2020; Soroka et al., 2016), age (Bachleda et
al., 2020; Kisley et al., 2007), education, income, political ideology, the Big 5 personality traits (Bachleda et al.,
2020) and prior attitude (Knobloch-Westerwick et al., 2017; Li et al., 2021; van der Meer & Hameleers, 2022).
Therefore, we propose the following hypothesis:

H2. Negativity bias is associated with gender, education and prior attitude.

According to the “selectivity model”, females are comprehensive information processors and males are selective
information processors, which means that females tend to focus on both subjective and objective product attributes
and respond to subtle cues, while males are inclined to use heuristics processing and miss subtle cues (Darley &
Smith, 1995). Related to negativity bias, while women show less negativity bias when seeking for information
(Bachleda et al., 2020), they pay more attention than men when exposed to negative information (Soroka et al.,
2016). Therefore, we propose the following hypothesis:

H2a. Negativity bias is associated with gender.

H2a.1. Women show less negativity bias in information seeking.

H2a.2. Women show more negativity bias in information processing

There were a few studies discussing the influence of age on negativity bias. Some studies showed a decrease in the
magnitude of negativity bias in adults with advancing age (Carstensen & DeLiema, 2018; Kisley et al., 2007) and it
seemed to be caused by a gradual age-related reduction in responding to negative images (Kisley et al., 2007). Age
is significantly correlated with years of education (Kisley et al., 2007), but only a few studies have examined the
effect of education on negativity bias. Education seems to be negatively associated with negativity bias (Bachleda et
al., 2020). Therefore, we propose the following hypothesis:

H2b. Negativity bias is negatively associated with education.

People with negative attitudes are more likely to seek negative rather than positive news to confirm their negative,
which is called confirmatory negativity bias (van der Meer & Hameleers, 2022). The result is in keeping with
studies on confirmation bias in selective exposure literature, which agree that participants with a negative attitude
had stronger confirmation bias (Knobloch-Westerwick et al., 2017; Li et al., 2021). Therefore, we propose the
following hypothesis:

H2c. Negativity bias is positively associated with prior attitude.

Cognitive Mechanisms in Sensemaking and Material Type
Cognitive mechanisms in sensemaking are the mechanisms that are used in the process and trigger changes in
concept. They can be broadly categorized into two groups: data-driven (bottom-up) and structure-driven/logic-
driven (top-down). Data-driven mechanisms involve identifying patterns of data and building on the patterns of
similarities and differences to create generalized abstractions of knowledge structures. Structure-driven/logic-driven
mechanisms involve making arguments or reaching conclusions with knowledge schemas and logic (Zhang &
Soergel, 2019). In the articles in our study, title, source, time and claim are typical formats of information that show
the structure of the article, while little structured knowledge is available in other parts of the text.

In the field of communication, evidence is usually regarded as “factual statements originating from a source other
than the speaker, objects not created by the speaker, and opinions of persons other than the speaker that are offered
in support of the speaker's claims” and has the function of persuasion. (McCroskey, 1969). According to a review, a
lot of evidence research focus on comparisons of different evidence types (testimonial assertion, factual evidence,
statistics, and the like), but it seems that persuasive effects have no difference across evidence types (Reinard, 1988).
However, there seems to be no literature reported regarding the influence of evidential attitude on the information
processing of different types of evidence. The sections of sample articles in our study include different evidence
types, such as illustrations, statistics, opinions, and facts.
There is no consensus in classifying information format and evidence type in the literature, so we refer to them as material types generally. Therefore, we propose the following hypothesis:

**H3.** Participants focus on different types of materials when reading positive and negative articles.

- **H3a.** The participants’ average fixation duration (AFD) is different when reading the same type of material in positive or negative articles.
- **H3b.** The participants’ average pupil diameter (APD) is different when reading the same type of material in positive or negative articles.

**METHODODOLOGY**

**Participants and Task**

We recruited 50 students from 23 different departments in a major Chinese university as participants, and a total of 43 valid eye movement data were collected in the experiment. Valid subjects included 9 freshmen, 12 sophomores, 6 juniors, 6 seniors, 4 graduate students and 6 doctoral students. There were 13 males and 30 females. All participants had a normal or corrected-to-normal vision and were native Chinese speakers. They received compensation between 60-100 yuan for their participation. Since there is no standard IRB-like procedure required for this kind of research at our institution, we did not go through an IRB application process. However, we made sure that the research followed similar ethical rules to ensure participants’ protection and privacy.

We selected 10 news articles on the three-child policy from various online sources. Five articles supported the three-child policy and five opposed it. The articles were similar in length, readability, and structure. They consisted of 10 types of formats, including title, time, source, introduction, illustration, claim, statistics, opinion, fact and conclusion. Each type of information corresponded to one or more areas of interest (AOIs) that we defined for eye-tracking analysis. The articles were presented in a random order to reduce the order effect (Figure 1). Participants could click on the headlines to view the detailed pages of articles (Figure 2).

**Data Collection and Analysis**

We collected the following data:

1. Pre-experiment questionnaire: we collected the demographic data and assessed prior attitude position and attitude strength concerning the three-child policy through questionnaires. See the section “Measures” for details.

2. Eye movement data: during the experiment, a Tobii Fusion eye tracker (250 Hz) was used to record the participants' eye movements.

3. Final report: after the experiment, the participants would finish a report, including their post attitude towards the three-child policy, their opinions and suggestions. The question asking for suggestions was “Please summarize your understanding of the three-child policy based on the reading material, and give policy suggestions (no less than 250 words)”. 

---

**Figure 1. List Page**
The eye-tracking and scale data were analyzed using the ErgoLab platform and IBM SPSS V27.0 software. We calculated several eye movement indicators for each AOI, such as average fixation duration and average pupil diameter. We used SPSS software to analyze the questionnaire data. We analyzed the experimental data using paired-samples T-test, paired-samples Wilcoxon signed rank test, Mann-Whitney U test, independent-samples T-test, one-way ANOVA test and Kruskal-Wallis test.

**Measures**

**Prior attitude**
To assess prior attitude strength, the questionnaire included similar items used in a previous study (Brannon, Tagler, & Eagly, 2007). The subjects indicated on 5-point scales how much knowledge they possessed on the three-child policy, how much they agreed that the three-child policy will help solve the population problem in China, how sure they were of their positions, how likely they were to change their attitudes, and how relevant the policy was to them.

**Negativity bias**
The negativity bias during information seeking, information processing and information are measured by the variables below:

1. The negativity bias during information seeking: number of selected articles (number of selected negative articles - number of selected positive articles), reading order (the average reading order of positive articles - the average reading order of negative articles), times of reading (the average times of reading negative articles - the average times of reading positive articles).

2. The negativity bias during information processing: reading time (the average time spent reading negative articles - the average time spent reading positive articles), AFD (one’s average fixation duration while reading negative articles - average fixation duration while reading positive articles), APD (one’s average pupil diameter while reading negative articles - average pupil diameter while reading positive articles).
3. The negativity bias during sensemaking: attitude change (post attitude – prior attitude).

The two variables related to eye movement are AFD (average fixation duration) and APD (average pupil diameter). Fixation refers to “a relatively stable eye-in-head position within some threshold of dispersion (typically ~2°) over some minimum duration (typically 100-200 mS), and with a velocity below some threshold (typically 15-100 degrees per second)” (Jacob & Karn, 2003). The length of fixation is a metric that is often applied in visual attention analysis and it’s generally believed that long fixation duration is correlated with high cognitive workload and higher cognitive effort (Borys & Plechawska-Wójcik, 2017; Jacob & Karn, 2003). The Pupil size indicates processing load and cognitive resource capacity (Kahneman, 1973). And there is a correlation between pupil response and emotional arousal that larger pupil diameter is associated with greater arousal (Gooding & Jackson, 2003).

**FINDINGS**

**Negativity Bias in Information Seeking**

In total, 29 of the 43 participants (67.4%) showed a negativity bias, seeking for more negative articles than positive articles. One subject selected only negative articles and no positive articles. Therefore, this subject was excluded from subsequent tests and the sample size was reduced to 42 (n=42). Seven participants (16.3%) showed no bias, selecting an equal number of negative and positive articles. Seven participants (16.3%) selected more positive articles than negative articles (Figure 3). We conducted a paired-samples Wilcoxon signed rank test and the results show that there is a significant negativity bias in the number of selected articles (Z = -3.754, p < 0.001). H1a.1 is supported.

![Figure 3. The Difference in the Number of Selected Articles](image)

In terms of reading order, 21 of the 42 participants (50%) showed a negativity bias, reading negative articles earlier than positive articles. Nine participants (21.4%) showed no bias, which meant that the average first reading order on negative articles was equal to that on positive articles. Twelve participants (28.6%) read positive articles earlier than negative articles. The results of the paired-samples T-test show that there is no significant negativity bias in the reading sequence (t = 1.414, p = 0.165). H1a.2 is rejected.

We did not limit the number of times the subjects read an article, so the subjects may read an article more than once and reinforce their ideas. In terms of the average number of times an article is read, 5 of the 42 participants (11.9%) showed a negativity bias, reading an individual negative article more often than a positive one. 33 participants (78.6%) showed no bias and 4 participants (9.5%) read an individual positive article more often than a negative one. We conducted a paired-samples Wilcoxon signed rank test and the results show that there is no significant negativity bias in times of reading (Z = -1.131, p = 0.258). H1a.3 is rejected. Therefore, H1a is partially supported.

**Negativity Bias in Information Processing**

In total, 26 of the 42 participants (61.9%) showed a negativity bias, spending more time reading an individual negative article than a positive one. 16 participants (38.1%) spent more time reading an individual positive article than a negative one (Figure 4). We conducted a paired-samples Wilcoxon signed rank test and the results show that there is a significant negativity bias in reading time (Z=-1.957, p = 0.050). H1b.1 is supported.
In terms of average fixation duration (AFD), 21 of the 42 participants (50%) showed a negativity bias, whose AFD is longer when reading negative articles than positive ones, and 21 participants (28.6%) saw the opposite result. The results of paired-samples T-test show that there is no significant negativity bias in the reading sequence ($t = 0.528$, $p = 0.600$). H1b.2 is rejected.

In terms of average pupil diameter (APD), 12 of the 42 participants (28.6%) showed a negativity bias, whose APD is larger when reading negative articles than positive ones, and 30 participants (71.4%) saw the opposite result. We conducted a paired-samples T-test. Contrary to the hypothesis, there is a significant bias that the participants’ average pupil diameter (APD) is larger when reading positive articles than negative ones ($t = 3.391$, $p = 0.002$), which means that the cognitive load is higher. H1b.3 is rejected. Therefore, H1b is partially supported.

**Negativity Bias in Sensemaking**

In total, 23 of the 43 participants (53.5%) changed their attitude negatively. 16 participants (37.2%) didn’t change their attitude and four participants (9.3%) changed their attitude positively (Table 1). We conducted a paired-samples Wilcoxon signed rank test. The results show that there is a significant negativity bias in attitude change ($Z = -3.290$, $p = 0.001$).

Table 1. Attitude Change
We consider information seeking to be balanced if the difference between the number of positive and negative articles read is less than or equal to 1, and there are 31 eligible samples. After balanced information seeking, 14 of the 31 participants (45.2%) changed their attitude negatively. 15 participants (48.3%) didn't change their attitude and 2 participants (6.5%) changed their attitude positively. We conducted a paired-samples Wilcoxon signed rank test. The results of paired-samples Wilcoxon signed rank test show that there is a significant negativity bias in attitude change after balanced information seeking (Z = -2.476, p = 0.013). Therefore, H1c is supported.

**Effects of Gender, Education and Prior Attitude**

First, we explored the influence of gender on negativity bias. Mann-Whitney U test and independent-samples T test show that gender has a significant effect on negativity bias in the number of selected articles (U = 94.5, p = 0.007) and APD (t = 2.206, p = 0.033) (Table 2). H2a.1 is partially supported. H2a.2 is partially supported. Both male and female participants selected more negative articles than positive articles, but the difference between the number of negative and positive articles selected by males is larger than by females (Figure 5). The APD of female participants was larger when they read positive articles than negative ones, while there was no significant difference between the APD of male participants when they read positive and negative articles (Figure 6). However, gender does not seem to have any impact on reading order (t = 0.863, p = 0.393), times of reading (U = 195.5, p = 0.851), reading time (U = 205.0, p = 0.667), AFD (t = -0.090, p = 0.928) and attitude change (U = 140.5, p = 0.151). H2a is partially supported.

![Figure 5. The Difference in the Number of Selected Articles Across Gender](image1)

![Figure 6. The Difference in APD Across Gender](image2)
We explored the influence of education on negativity bias. Results of the Kruskal-Wallis test and One-way ANOVA test show that education has no significant effect on negativity bias by any measure: number of selected articles (H = 4.588, p=0.101), reading order (F = 0.800, p = 0.457), times of reading (H = 2.408, p = 0.359), reading time (H = 3.440, p = 0.179), AFD (F = 0.295, p = 0.746), APD (F = 0.757, p = 0.476), attitude change (H = 2.160, p = 0.340). H2b is rejected.

We conducted a Kruskal-Wallis test and a One-way ANOVA test to explore the influence of prior attitude on negativity bias. The results show that prior attitude has a significant effect on negativity bias in attitude change (H = 11.371, p = 0.010) (Table 2). Participants with more positive prior attitudes changed their attitudes more negatively. However, prior attitude does not seem to have any impact on the number of selected articles (H = 1.182, p = 0.757), reading order (F = 0.028, p = 0.994), times of reading (H = 2.444, p = 0.485), reading time (H = 1.181, p = 0.758), AFD (F = 0.174, p = 0.914), APD (F = 1.000, p = 0.403). H2c is partially supported. Therefore, H2 is partially supported.

Table 2. Summary of significant test results. (*p < 0.05, **p < 0.01)

**The Focus of Attention on Different Material Types**

Focusing on the difference in AFD and APD on participants’ preference for material types in the body of the articles when reading positive and negative articles, we conducted paired-samples T-test and paired-samples Wilcoxon signed rank test. The results show that AFD was longer when participants visited the areas of interest for claims in the negative articles than those in positive articles (Z = -2.069, p = 0.039). What’s more, APD was larger when participants visited the areas of interest for illustrations (t = 4.636, p < 0.001) and opinions (Z = 2.432, p = 0.015) in positive articles than those in negative articles.

**DISCUSSION**

Our findings confirm the existence of negativity bias in information seeking, information processing and sensemaking. People sought more negative articles and spent more time reading individual negative articles. In terms of sensemaking, they changed their attitude negatively. In particular, people with balanced information seeking also changed their attitude negatively, which confirmed the negativity dominance (Rozin & Royzman, 2001). Inconsistent with H1b.3, the participants’ APD is larger when reading positive articles than negative ones, which means that the cognitive load is higher. The explanation may be that positive information can lead to more complex cognitive processes, for example, positive information drives people to search more for explanations (Krull & Dil, 1998; Llu, Karasawa, & Weiner, 1992; Unkelbach et al., 2020).

We also examined the influencing factors of negativity bias. Our findings suggest that in terms of the number of selected articles, the males had a stronger negativity bias. This result can be well explained by the “selectivity model”, in which females are seen as comprehensive information processors and males are seen as selective information processors. In terms of APD during reading, only females had a greater cognitive load when reading positive articles than negative articles, while no such difference was shown among males. However, it seems to be contrary to the conclusions of previous research (Soroka et al., 2016). It is worth mentioning that the three-child policy is a highly gender-related topic, so the findings need to be considered in a limited setting.

Our study also found that people with more positive prior attitudes changed their attitudes more negatively, which is in line with the discovery in selective exposure literature (Knobloch-Westerwick et al., 2017; Li et al., 2021). People
with positive attitudes are more likely to be influenced by negative information, while people with negative attitudes hardly change their attitudes. To some extent, it confirms the powerful effect of negative information.

Findings suggested that AFD was longer when participants visited the areas of interest for claims in the negative articles than those in positive articles, and APD was larger when participants visited the areas of interest for illustrations and opinions in positive articles than those in negative articles. People show different cognitive patterns of attention when reading positive and negative articles. It seems that people pay more attention to the structural feature of articles while reading negative articles, which shows a structure-driven/logic-driven cognitive mechanism. On the contrary, while reading positive articles, people focus more on “data”, which shows a data-driven cognitive mechanism. Negative news often triggers negative emotions, which may lead participants to be more careful and thoughtful about what they read in order to avoid drawing wrong conclusions or overreacting to information. Therefore, the structure-driven/logic-driven cognitive mechanism may help the reader process this information better. On the contrary, people's tendency toward data-driven cognitive mechanisms when reading positive news is probably because these articles often contain emotional content and descriptions that are more likely to elicit empathy and emotional resonance from readers. In addition, positive articles usually don't require much logical analysis or reasoning because their content is likely to be more straightforward and easier to understand and absorb. However, it should be noted that this explanation won't work in all cases, as individuals' cognitive and reading preferences may vary based on individual characteristics.

CONCLUSION AND LIMITATIONS
We conducted an eye-tracking experiment to examine negativity bias during information seeking, processing and sensemaking about a policy debate, namely the three-child policy in China. We found that participants showed a preference for negative articles over positive articles in their selection and reading behavior, and that reading negative articles resulted in lower cognitive load and more negative attitude change than reading positive articles. We also found several influencing factors including gender and prior attitude affected negativity bias, and participants used different cognitive strategies when making sense of positive and negative information.

The findings contribute to a better understanding of negativity bias in the overall process of information seeking, processing and sensemaking, which may help to design news systems that can adapt to the preferences and needs of different users to improve user satisfaction and engagement with news content. Instead of feeding people with contents that people are most likely to click, news services should provide users with information from both positive and negative sides, to reduce the impact of negative bias, and help them better cope with controversial topics and make decisions.

Our study had some limitations to be acknowledged. First of all, our study was conducted in April 2022, when the pandemic was still ongoing and limited our recruitment of participants outside the university, leading to a homogeneous sample of students from the same school. Secondly, the three-child policy was implemented in May 2021 and sparked public debate for about a year before our experiment, which might have influenced the participants' exposure to and processing of the materials related to the policy prior to our experiment. Third, our study used prototype pages and edited materials to present the articles, which might not reflect the actual online news environment that readers encounter. Fourth, negativity bias for one topic cannot be generalized to other topics. Future research could address these limitations by conducting experiments with real news articles and websites after the implementation of the policy, and by measuring emotional responses and neural activity during information seeking, processing and sensemaking. Although our experiment demonstrated the existence of negativity bias in information seeking, processing, and sensemaking of a policy debate, it did not explain how and why negativity bias occurs. Future research can also examine the links between behavior, emotion and cognitive mechanisms of negativity bias, which could provide more insights into how people process positive and negative information.

What Is a Person? Emerging Interpretations of AI Authorship and Attribution

Moulaison-Sandy, Heather
University of Missouri, USA | moulaisonhe@missouri.edu

ABSTRACT
Recently, the scholarly community has been eagerly exploring how AI-produced content should be integrated into both academic writing and scholarly publishing. This paper investigates the prevailing responses to the introduction of ChatGPT in November 2022 and the interest that has been afforded it by both the academy and the publishing industry. A review of the published literature on aspects of ChatGPT authorship was carried out, finding that government and the publishing industry have unequivocally asserted that large language models (LLMs) like ChatGPT do not possess the traits of a person and are not able to author texts as a result. Other approaches, including practice, have been less vehement. To assess the integration of instructions on referencing ChatGPT using APA, top Google hits in the .edu domain were collected and analyzed over a 6-week period from March 14 to April 18, 2023, a time during which official recommendations of the APA Style were finalized. Findings reveal that librarians were quick to provide guidance, but slow to update that guidance, contributing to the potential for misunderstanding the affordances of and best practices for work with LLMs.

KEYWORDS
Large language models (LLMs); ChatGPT; authorship; attribution; library webpages.

INTRODUCTION
ChatGPT (https://openai.com/) is a large language model (LLM), a type of artificial intelligence (AI) that uses machine learning to function as a “word prediction machine” (North, 2023). Using a corpus of web documents harvested in 2021 as a basis, ChatGPT generates text in response to user prompts. Unlike web search engines that provide websites as hits in response to a query, generative AI tools like ChatGPT do not provide responses based on highly ranked sources; in fact, they do not answer questions. Instead, they pull together text in response to a prompt. In other words, they ghostwrite text based on the combinations of words that appear in their training corpus (Crotty, 2023) to generate “statistically probable outputs” (Chomsky et al., 2023, para 2). These systems function as black boxes, which has the potential to allow them to be anthropomorphized and described as thinking and perceiving when instead they are processing (Ballardini et al., 2019). In using web-based sources as their inputs, LLMs produce texts that often seem to be plausibly-written content, including potentially sonnets, analyses of books, scripts, essays, and others that can be produced in the style of living scholars, politicians, and celebrities (e.g., Houston & Corrado, 2023).

Generative AI is a powerful tool with the potential to revolutionize industry, education, and even society. Concern about the use of text authored by generative AI tools in scholarly publishing and in education surfaced almost immediately after the emergence of ChatGPT (e.g., Dans, 2023) with problems highlighted such as the difficulty in identifying AI-generated text (e.g., Nature, 2023), the emergence of educational deficiencies that will interfere with future scholars’ abilities to reason (e.g., Civil, 2023), and the need to train users to better input their prompts to the LLMs (aka “prompt engineering” (Bridle, 2023)) (e.g., Nield, 2023) to optimize results. LLMs are unquestionably being used by authors, at times unscrupulously. In Science, Thorp (2023) explains that “in a recent study, abstracts created by ChatGPT were submitted to academic reviewers, who only caught 63% of these fakes. That’s a lot of AI-generated text that could find its way into the literature soon” (p. 313).

In computer science and related fields, studying LLMs and other generative AI tools is not new. Evaluation of the efficacy and accuracy of LLMs has been ongoing for tasks such as email auto-complete texts (e.g., Chen et al., 2019; Robertson et al., 2021), deductive coding in qualitative research (Xiao et al., 2023), and helping students learn to write computer code (e.g., Leinonen et al., 2023; MacNeil et al., 2023). The ethics of LLMs (e.g., Abid et al., 2021) and social justice pertaining to AI, including the problem of disparate impact (e.g., Kartal, 2022; O’Neil, 2016) have also been considered. Much less frequent in the literature are studies investigating how LLMs are used in writing. Authorship using generative AI tools like ChatGPT has been studied in a limited capacity from a computer-science perspective (e.g., Draxler et al., 2023, Yuan et al., 2022) and from a policy perspective (e.g., Ballardini et al., 2019). However, given the newness and almost instant ubiquity of ChatGPT, at present the published, peer-reviewed literature does not take into account the freely available and enthusiastically discussed new tool. This paper aims to fill that gap in understanding how authorship is being considered at present in this emerging environment.

Since ChatGPT became widely available in November 2022, there has been interest in citing AI-authored texts. Initial recommendations by APA in January (APA Style, 2023) endorsed their consideration as “Personal.
Communications” (abandoned by mid-March 2023) or “Webpages” (APA Style, 2023; S. Lazer, personal communication, 2023). Later, emails from the APA style guide began recommending they be cited as software (e.g., S. Lazer, personal communication, 2023). During this time period, which coincides with the winter semester in many North American universities, interim guidance was needed for students and instructors alike, as academia began adjusting to the challenges of freely available LLMs and their place in the academy.

APA Style officially came forth with an approach to citing generative AI tools like ChatGPT on April 7, 2023. The final recommendation to cite the text as “Software” (McAdoo, 2023). Since the text is not authored by a “person” nor is it consultable or reproducible, the solution is not without problems. As word continues to trickle down in this evolving information space about the evolution of best practices, research and practice have been particularly eager to arrive at an understanding of the best way to help users engage with the texts, especially in light of the ethical implications that are in the process of being discovered. The current paper examines the literature in this rapidly changing space as it relates to authorship, and it likewise investigates top recommendations for citing generative AI texts using APA as described on library sites in the .edu domain.

As approaches to considering AI authorship unfold, this paper seeks to address the following research question:

RQ: How are recommendations for citing ChatGPT in APA presented on academic library webpages in the .edu domain, and by which institutions?

This paper begins with a review of published resources on the topic of authorship and LLMs, which remain sparse and largely un-peer-reviewed due to the newness of the ChatGPT tool. The research question will then be investigated through an analysis of resources promoted by academic libraries in response to ChatGPT with a focus on citing with the APA style guide.

**REVIEW OF THE LITERATURE**

Focusing on the conversation around generative AI authorship that is emerging in scholarly communication since ChatGPT became available, a range of sources was investigated relating to four topics: intellectual property considerations, errors in generative AI-authored texts, emerging policies in scholarly publishing, and emerging guidance in academic libraries for referencing text created by LLMs.

**Ownership, Copyright, and Plagiarism with LLMs**

On March 16, 2023, the U.S. Copyright Office indicated that content produced through the use of generative AI tools like ChatGPT do not meet the requirements for human authorship needed to secure copyright. This is in alignment with “both copyright and patent laws in Europe [that] have relied upon the concept of author or inventor as a natural person” (Ballardini et al., 2019, p. 118). Although “some systems operate in response to a user’s textual instruction” (U.S. Copyright Office, 2023, p. 2), the prompt supplied by users is not enough input to claim human authorship. Web-based sources used as training documents for these LLMs can be copyright protected. However, the language that emerges from a generative AI tool predicts the next word in the series. The details of the text as well as the authorship of the original corpus documents have been lost, leaving only ownership of the corpus and the generative AI tool itself.

Creatorship and perceptions of creatorship, however, are not one in the same. In one of the first papers (an unreviewed manuscript) to look at the question of perceptions of authorship and ownership as they pertain to generative AI, Draxler and colleagues (2023) conclude that user perceptions of authorship are not straightforward when GPT-3 is being used for postcard authorship. Study participants were less inclined to claim authorship of the generated text when they thought a human ghostwriter had been involved. This distinction between perceptions of ownership when authorship is human or AI reflects the U.S. governments’ definition of plagiarism, which is “the appropriation of another person’s [emphasis added] ideas, processes, results, or words without giving appropriate credit.” (U.S. Code of Federal Regulations, 2023). Users were less inclined to consider their own the content that a human wrote; content authored AI, however, they more readily considered ownership over. Even though LLMs are ghostwriting based on what is likely to be copyright-protected works that are the product of human authorship, perceptions of plagiarism might be less acute if there is an increased perception of agency in the writing of the prompts as reflected in shaping the final product of the LLM (Draxler et al., 2023).

**Accuracy and Hallucinations in LLMs**

One aspect of ChatGPT that emerges with its misuse as a question-answering system is that it (like other LLMs) will yield incorrect information (Chiang, 2023); in the case of ChatGPT, incorrect information is produced roughly 20% of the time (Woodie, 2023). Instances where information is fabricated are called “hallucinations” (Bowman, 2023; Chiang, 2023, Woodie, 2023). ChatGPT is a text transformer; “all it does is guess what the next word in the phrase is … It produces generic, milquetoast output that’s confidently wrong about a lot of things” (Scott, 2023, 7:18). As such, it is not designed to provide factual information in response to prompts, despite the convincing nature of the text produced.
Chiang explains that hallucinations are “compression artifacts … if a compression algorithm is designed to reconstruct text after ninety-nine per cent of the original has been discarded, we should expect that significant portions of what it generates will be entirely fabricated” (Chiang, 2023, para 8). Plausible-sounding reference sources, therefore, need to be confirmed (Chiang, 2023); this is because well-known experts may be cited in the text that is produced, and titles of realistic-sounding resources provided, but both are a function of the content in the corpus. They are not factual, though they sound deceptively convincing.

Hallucinations are not unique to ChatGPT. Google’s Bard (https://bard.google.com/) AI Chatbot (another LLM) had similar problems with putting forth accurate answers to the question of notable discoveries from the James Webb Space Telescope in a test post. Bard inaccurately claimed the telescope was the first to image planets outside of the solar system. The Guardian reported that this was a problem of “the chatbot repeating errors from the information that it absorbs” (Milmo, 2023a, para 9), which is potentially another factor affecting the hallucinations that emerge. Already, in 2016 Microsoft’s AI Twitter bot was provided racist, anti-Semitic, and sexist training data in the form of tweets by Twitter users that it then repeated back; the bot was inactivated after less than a day (Tennery & Cherelus, 2016). As of March 21, 2023, when public access to Bard began to roll out, Google has been actively seeking input from users to correct the inevitable hallucinations and is providing seamless access to Google search results as well (Hsiao & Collins, 2023).

**Authorship and Attribution in Scholarly Publishing**

As of March 14, 2023, a series of editorials had already been published in *Science, Nature,* and *JAMA* (Griffin, 2023), and the arXiv repository (ame5, 2023). All of the sources rejected generative AI tools as authors because authorship carries responsibilities that AI cannot meet. This is similar to the U.S. Copyright Office’s statement of policy (2023). In addition, the journal statements did not support the inclusion of text authored by an LLM. For *Science,* this is because work must be original, and not “plagiarized” via the LLM (Thorp, 2023). *Nature,* instead, focuses on the ethical aspects of participating in scholarly communication that include the importance of transparency and integrity (Nature, 2023). ArXiv, however, sees ChatGPT and other LLMs as one of the many tools that scientists may use in their work, and is permitting its use (ame5, 2023).

One aspect of writing that traditionally has not merited the designation of “author” is that of “editor.” In several of its journals, Elsevier is proposing the use of AI as a ghostwriter to provide language editing support. In this scenario, authors “should only use these technologies to improve readability and language” (Elsevier, 2023). Staiman (2023) expresses a call for LLMs to be used in support of social justice. Because the majority of the world’s researchers are not native speakers of English, and because expression is nonetheless an essential aspect of scholarly communication, opening the use of LLMs to EAL (English as an Additional Language) authors is a way of allowing review to focus on the quality of the work rather than on potential language-related concerns.

The scholarly publishing community’s interpretation is largely in contrast to the guidance provided by OpenAI (2022), which outlines when it is permitted to publish content with attribution to the enterer of the prompt. Those who enter prompts are considered “creators” by OpenAI, and are permitted to publish ChatGPT-generated content as follows:

- The published content is attributed to your name or company.
- The role of AI in formulating the content is clearly disclosed in a way that no reader could possibly miss, and that a typical reader would find sufficiently easy to understand.
- Topics of the content do not violate OpenAI’s Content Policy or Terms of Use, e.g., are not related to political campaigns, adult content, spam, hateful content, content that incites violence, or other uses that may cause social harm.
- We kindly ask that you refrain from sharing outputs that may offend others. (OpenAI, 2022, “Content co-authored”)

In education, however, more tolerance for the extent of use of LLMs has been signaled. The International Baccalaureate (https://www.ibo.org/), an exam indicating preparation for post-secondary education, is allowing students to cite ChatGPT (Milmo, 2023b) giving rise to a Twitterstorm of concerns about how little LLMs are understood. Education overall is eager to understand how best to use LLMs (e.g., Civil, 2023; Dans, 2023).

**Style Guide Interpretations for Citing LLMs**

Even if major journals refuse to publish the ghostwriting of generative AI tools and if the texts are infused with errors, this does not mean that writers, including students, will not be eager to outsource work to authoritative-sounding ghostwriters and to cite that work.

The Modern Language Association style guide (MLA) already declared how to cite artificial intelligence in 2019 (MLA Style, 2019) in its 8th edition; however, the technology was not as advanced then as it is now. In late 2022,
The Atlantic published an article by Stephen Marche entitled “The College Essay Is Dead” in which concern was expressed for the humanities in this new environment. No further update from MLA about the use of text authored by generative AI has been found.

The American Psychological Association’s style guide (APA) was less proactive than MLA regarding AI-generated texts, but since the emergence of ChatGPT, APA has been actively collecting data about its use (S. Lazer, personal communication, March 12, 2023). Initially, APA gave guidance to writers wishing to cite ChatGPT or other generative AI tools via a tweet on January 10, 2023 (APA Style, 2023). In that tweet, it set out recommendations based on two options: 1) if the text is retrievable, it should be referenced as a webpage (i.e., an electronic source), 2) if the text is not retrievable, it should be treated as a personal communication. With the rapid changes to the lay understanding of ChatGPT, APA Style modified its approach by mid-March of the year (S. Lazer, personal communication, March 12, 2023). Information about the revised approach was not immediately captured, however, formally on Twitter or on the APA Style blog, even though both were indicated as places to watch.

After the time that APA published the January 10, 2023, tweet in response to a user’s question, it appears to have been silent on the matter of how to cite ChatGPT and other LLMs until April of this year.

On March 12, 2023, the updated instructions about citing ChatGPT communicated by email were to pivot to capturing as much information as possible from the interaction with ChatGPT and citing it as computer software. That recommendation was the following:

But for paraphrasing, quoting, or providing the full text response from ChatGPT, a reference is needed (following the general format of a software reference, as seen in Section 10.10 of the Publication Manual):

OpenAI. (2023). *ChatGPT* (Feb 13 version) [Large language model]. https://chat.openai.com/chat

Sample citation: (OpenAI, 2023) (Stefanie Lazer, personal communication, March 12, 2023).

On Friday, April 7, 2023, the APA blog for the Style Guide (McAdoo, 2023) posted the approach to citing APA that is endorsed at present: as was the recommendation communicated by email in mid-March, text produced by ChatGPT will be roughly considered Computer Software, but unlike most content created by computer software, ChatGPT text cannot be recreated. Given the complexities of the tools, writers should be explicit about their use of the resource as possible and provide as much information as possible, including in the methodology and as appendixes. The suite of recommendations from the mid-March email held, including mentioning the use of ChatGPT elsewhere if a methodology section was not included in the paper and saving the transcript and recording the prompt, and including them as an appendix if possible, or otherwise making sure they are accessible.

**METHOD**

To address the research question, data from academic library webpages on citing ChatGPT in APA was captured once per week for six weeks from the .edu domain, a domain “intended for accredited U.S. postsecondary institutions” (Educause, 2023, General, para. 1); historically, there are between 7,000 and 8,000 postsecondary institutions in the .edu domain (.edu, 2023). Starting Tuesday, March 14, 2023, and every Tuesday thereafter until April 18, 2023, the search query “chatgpt apa citation site:.edu” was launched in Google. Three pages of results were captured each week and coded in MAXQDA. Google was set not to personalize results in order to provide a more complete set of hits. An analysis of the pages was carried out weekly as a way of assessing changes in the number of pages on the topic and the extent of their contribution.

For each page of results, the academic institution name associated with the library promoting APA reference support was recorded and classified using The Carnegie Classification of Institutions of Higher Education (https://carnegieclassifications.acenet.edu/institutions/). Concurrently, inclusion among Association of American Universities (AAU) was also recorded. Visualizations for the data collected were created using Excel. The data associated with this project is available at [redacted].

**RESULTS**

Over the 6-week period of study, the number of relevant webpages in Google changed, as well as the order of the most highly-ranked pages and the content on those pages themselves (see Table 1). This study focuses primarily on the set of webpages collected weekly, in the aggregate.

### Institutional Classifications

Based on the name of the institution associated with the webpages retrieved, the Carnegie institutional classification was recorded. Doctoral Universities were the most common class of institution posting information to its library about using APA to reference ChatGPT. A somewhat unexpected number of Baccalaureate Colleges, Baccalaureate/Associate's Colleges, and Associate’s Colleges were likewise represented among the top three pages of hits. See Figure 1 for the Carnegie classification breakdown.

![Top Results for APA Citation Information by Carnegie Classification](image)

**Figure 1. Institutional Classification, by Week**

Of the doctoral institutions, relatively few Association of American University (AAU) member institutions’ libraries were included among the top hits in the first part of the study. After the APA Style’s official publication of guidance, however, the number of AAU institutions increased. See Figure 2.
Inclusion criteria for the study required pages to address referencing ChatGPT using the APA style guide. The range of information provided on individual webpages, however, varied greatly. Generally, throughout the study over half of the pages indicated in some fashion that recommendations were either interim or were evolving on the part of APA and other style guides. See Figure 3 for a graphical representation of this data.

**Timely and Accurate Guidance**

By the time data collection had begun in mid-March, 2023, the APA was no longer recommending that ChatGPT be treated as an 1) Electronic source or as a 2) Personal communication (S. Lazer, personal communication, March 12, 2023). Nonetheless, some top-ranked pages still recommended these practices. Figure 4 shows the percentage of pages recommending either one or both of these two approaches that were no longer endorsed by the APA at the time, demonstrating the extent to which stale recommendations were propagating the web as highly-ranked sources via Google and contributing to the potential for amplifying misinformation in this space.
Although 1) ChatGPT is a language prediction model and is not a chatbot to supply factual responses, and 2) ChatGPT’s corpus was harvested in 2021, well before the current version of ChatGPT came to prominence, top-ranked library sites have nonetheless asked ChatGPT for guidance in creating APA citations and have published that guidance verbatim. To ask ChatGPT for help with citing itself is a tongue-in-cheek approach to an ostensibly serious topic, that of authorship, attribution, and potentially ownership of intellectual property; it is fundamentally misguided, however, demonstrating a misunderstanding of the capabilities of LLMs and the ways in which they can be used in academia. See Figure 5 for the prevalence of using this approach among top pages. Of interest is that in the final week of the study after the guidelines had been released for over a week, the first page of Google hits included 3 webpages that continued to present this recursive approach, but none of the webpages on the second or third page of hits did. All three webpages on the first page of results had ranked on the first page throughout the period of study, implying that Google is cautious in quickly changing the order of its results.

Updates Relating to the April 7, 2023, Blog Post
The APA Style blog formally published guidance for referencing ChatGPT on Friday, April 7, 2023 (see McAdoo, 2023). On Tuesday of the following week at the time of data collection, none of the pages in the top three pages of hits fully reiterated this information, though one Doctoral University provided a link to McAdoo’s APA Style blog post, and another Doctoral University featured the blog post’s title, “How to cite ChatGPT” in its APA blog roll.
Figure 3 captures out-of-date recommendations throughout the period of study, but since formal guidance was published on April 7, not only should the incorrect recommendations be replaced as quickly as possible after that point, but the most recent and accurate information should be provided and cited from that point onward.

During the final week of study (week 6, April 18, 2023), data was collected 11 days after the publication of the official guidance from APA as posted to the APA Style blog (McAdoo, 2023). Looking closely at the first page of hits from that week, of the 9 working webpages (one page retrieved a 404 error), 3 were from Doctoral Universities, 3 from Master’s Colleges & Universities, and 3 from Associate’s Colleges. See Table 2.

Table 2. Summary of content on the first page of Google hits, April 18, 2023

Table 2 focuses on the first page of results in Google, as they appeared over one week after the formal guidelines were published. This timeframe was chosen because it gives ample time to librarians to become informed about the changes and to address them on the web. In terms of timeliness, only 3 of the 9 pages in the first page of Google hits included the link to the APA Style blog’s post about citing ChatGPT. None explained how to interpret the content, though one did provide the example from the page. Over half of the webpages on the first page of Google hits continued to give out-of-date recommendations, including one Associate’s institution that provided a link to the April 7, 2023 APA Style blog post, as well as links to earlier recommendations on other sites, and then as content provided two different responses from ChatGPT in regards to the question of referencing itself. On that webpage, wording that preceded the ChatGPT-generated text states “ChatGPT suggests” which anthropomorphizes ChatGPT in a way that is consistent with some of the literature consulted.

In terms of accuracy, over half of the webpages on the first page of Google hits included out of data recommendations to cite ChatGPT text as a personal communication. Two webpages recommended the current best practice that users save the transcripts generated and the prompt used to query the system and make them both available. One webpage provided guidance when transcripts were saved; the rest of the webpages were silent on the topic.

**Other Information Provided**

Some highly-ranked pages offered additional insight and guidance on the topic of citing ChatGPT using APA. For example, many pages correctly included recommendations to clearly indicate in the writing project that ChatGPT was used as a source, to include ChatGPT transcripts as an appendix, and to record the prompt used to query ChatGPT. Many pages also cited official APA style guide sources such as the tweet from January 10, 2023 (the recommendations of which regarding electronic sources and personal communications were replaced by the time of data collection (S. Lazer, personal communication, March 12, 2023)). Other libraries cited sources that were less authoritative, including several that linked to a page from the University of Guelph and Scribbr.com. Finally, some pages warned against using ChatGPT as a question-answer system due to the problems of hallucinations where ChatGPT made up not only content but also reference sources.

**DISCUSSION**

ChatGPT is a topic of great interest to the scholarly community, but one that, universally, is not well understood. The way to credit texts produced by ChatGPT and other LLMs has been challenging to address. The APA itself issued interim guidance that it ended up quickly reversing, as APA like publishers and government entities, came to the conclusion that ChatGPT is not a “person” and the text it produces cannot be treated as being intellectually similar to the writings of individuals. This has not deterred academic library sites in the .edu domain from providing guidance on how best to cite ChatGPT or other generative AI tools, and for Google to provide these pages as hits. This is despite the most highly ranked pages on the first three pages of hits often providing inaccurate or out of date information. The newness of the topic, the unfamiliarity on the part of librarians with LLMs and authorship in this space, and the lack of consensus on which Google could develop rankings for its results has created an environment
in which some of the most highly ranked hits, especially during the first part of the study, were not always providing good results.

Over time, the quality of the recommendations provided on the top sites stayed roughly the same. For example, the percentage of top webpages that indicated the space was evolving (Figure 3) remained largely consistent, despite the APA Style guidelines that emerged that solidified the recommendations. Webpages continued to provide outdated guidance even after the April 7, 2023, announcement (see Figure 4 and Table 2). Finally, over time, a positive trend was finding fewer instances of guidance for citing ChatGPT that were provided via a ChatGPT query (see Figure 5); as indicated in Table 2, however, during the final week of the study, all three webpages that asked ChatGPT were found on the first page of Google hits.

One unanticipated finding was the nature of the academic institutions that Google ranked highly. Many were not research-intensive institutions helping to support graduate education and research faculty, but rather were 2 or 4-year institutions of higher education primarily serving undergraduate education and the educators who support these groups. No AAU libraries were listed among the top hits, and during the first few weeks of data capture, there were only slightly more institutions serving graduate populations as ones serving undergraduate populations (week 1: 8 graduate/7 undergraduate; week 2: 9 graduate/6 undergraduate; see Figure 1). Questions remain as to why large, elite research institutions were generally unrepresented in these top-rated hits on Google: were librarians at those institutions cautiously waiting to provide information only after the APA had released definitive guidelines, or conversely, did they assume that researchers would adhere to the guidance provided through their journals, making specifics of providing guidance moot, but leaving it needed at the undergraduate level? An additional possibility is that they understand the potential for problems with accuracy and hallucinations given the functioning of LLMs and presume that researchers at the graduate level will desire full ownership over their own writing, partly as a way to ensure its accuracy.

What Is Not Captured in the Study Results

The review of the literature demonstrates that a good deal of interest has been generated around the question of how like a person ChatGPT is. Publishers and the government, entities fundamentally interested in the creative power of individuals and the rights they have to that intellectual content have dismissed ChatGPT and other LLMs, based on a thorough understanding of how AI works, as being neither like a human in terms of authorship capabilities or creative ones. Other literature is more engaged with interacting with ChatGPT to generate text. These pieces are not always rigorous in their understanding of the nature of LLMs (e.g., Roose, 2023), believing themselves to be in conversation with the AI (Ballardini, 2019). At the beginning of the current study, 40% of library sites engaged with ChatGPT to identify best practices for citing it in APA, an approach that is fundamentally flawed for the reasons described in the results, but that demonstrates nonetheless a certain sophistication on the part of the librarians. These librarians understood that ChatGPT could respond to prompts running a gamut of topics and had created accounts and done the initial legwork demonstrating nonetheless a degree of sophistication.

The results also seem to reflect some of the tensions perceived in the literature in terms of the interest in LLMs accompanied by a lack of knowledge about basics of how they work. Given the variations in the correctness of the recommendations and the thoroughness of the information provided on the webpages, there is a sense that those who understood the technology more robustly preferred not to go on record publicly with guidance or recommendations. Conversely, those who were less sophisticated in their understanding were eager to engage with the technology, for example, by asking ChatGPT about referencing itself (Figure 3). This is consistent with the naïve approach adopted by the New York Times anthropomorphization of Bing’s AI chatbot (Roose, 2023; cited in North, 2023) and other prominent sources that unwittingly personify their interactions with the LLMs, as if they are interacting with humans. Although tongue-in-cheek, the recursive approach adopted by librarians who asked ChatGPT to describe how best to cite itself demonstrates a fundamental misunderstanding of the nature of LLMs as text prediction machines and not as chatbots. This, as well as the out-of-date information posted to pages, information provided by information professionals who claim expertise in this area, had the potential to contribute to the confusion around the nature of LLMs, the quality of their texts, and the place of these texts in the scholarly conversation.

Ultimately, the question of how best to help novice scholars seems to be key. If librarians at institutions with primarily undergraduate populations felt the need to address questions of how to reference ChatGPT, the need must be present. These are the individuals who are most in need of understanding how to ensure they are representing the origin of the intellectual property included in their class papers, which is admirable to see.

Limitations

Limitations to this project include the problem of relying on Google for ranked results, and using a single search string that focuses on ‘APA citation’ within academic libraries in the U.S. Because Google is the dominant search engine, this problem is nonetheless likely replicated by scholars, especially junior scholars, seeking support for their own work citing ChatGPT. Other limitations include the problem of manually coding a large set of documents,
though the use of MAXQDA is intended to help mitigate this to an extent. Finally, this project does not break out webpage content by class of institution in the results. It assumes that practice is concerned with providing accurate and timely information on citing ChatGPT in APA. Some libraries supporting junior scholars, however, might reasonably have priorities that focus on other aspects of the problem, such as working with instructors to assess the applicability of ChatGPT texts to the assignment. In assuming that all libraries should provide the same level of content, a limitation is created that does not account for differences among institutions and their target users.

CONCLUSION
Much more work in understanding authorship, attribution, and ownership remains in the system of scholarly writing practices as they pertain to texts produced by LLMs. Government bodies have led the way in formally designating the writing of LLMs as being the product of algorithms that predict text based on a corpus, and as such are not creating text, nor as machines do they have the intellectual capacity to do so. Publishers have followed this lead, indicating that LLMs are incapable of the intellectual effort required for authorship of an article, for example, and in many cases should not be cited due to the problem of inaccuracies that are introduced. Education, however, shows evidence of being split, with some looking to integrate the tools of the future, and with others focusing on the problematic nature of the content produced, including the hallucinations that stand in the way of accuracy.

Since the release of ChatGPT in November 2022, individuals, including writers for the New York Times and possibly librarians, have become enthralled by the seemingly realistic nature of the interactions and have enjoyed reading the words not as the results of a text prediction model, but rather as being accurate and reflecting thoughts and feelings. Although the entertainment value seems compelling, there is nonetheless a sense that those in the position of being thought leaders in this space have an obligation to be informed about the nature of the interactions before accepting them at face value and perpetuating inaccurate approaches to considering the products of these algorithms.

Noam Chomsky and colleagues (2023) indicate that LLMs “are incapable of distinguishing the possible from the impossible. . . . For this reason, the predictions of machine learning systems will always be superficial and dubious” (para 10). Practice is placed in the difficult position of supporting users in this nebulous and rapidly changing environment. Yet, at the same time, a professional obligation to understand the basics of the technology prior to addressing it publicly remains. Were all librarians reticent to undertake the self-study needed, no pages of guidance would have been found in conjunction with this study, which one might imagine to be worse than inaccurate guidance, if a lack of guidance (either on the APA blog or on a library’s site) could be taken to imply that references are not needed. But, in fact, references are needed. Information professionals are not infallible; many provided information that was up to date and accurate, reflecting best practices that APA itself had not published. Others insisted on the notion that this is a time of interim guidance, which was accurate.

ABSTRACT
Today there is increasing emphasis on knowledge exchange (KE), the movement of knowledge and expertise amongst diverse groups to enhance research uptake, use, and impact in healthcare, government, and community settings. Library and information science (LIS) professionals are central actors in KE through community engagement, scholarly communication, literacy, and cultural heritage initiatives, but (how) is this work formally documented and evaluated? Through interviews with 24 information professionals working in varied settings, we considered how KE activities fit into the current library assessment and evaluation landscape. Using thematic analysis, we identified challenges with placing this work within current assessment practices and evaluation frameworks and showing its value, as well as a desire for alternative, more dynamic assessment and evaluation methods. We discuss these findings with respect to previous research in LIS and KE more broadly to consider professional and organizational implications.

KEYWORDS
Library assessment and evaluation, knowledge exchange, community-engagement, relationship building, information professionals

INTRODUCTION
Today there is increasing emphasis on knowledge translation, mobilization and exchange in healthcare, government, and community settings (Carson & Given, 2021; London School of Economics (LSE), 2023). These terms are sometimes used synonymously and at other times favored by specific disciplines or groups (Shaxson et al., 2012). All emphasize moving research into action, the involvement of multi-sectoral actors in applying research findings (Nutley et al., 2007; Redman et al., 2015; Weiss, 1979), and a desire to show impact. Research impact is defined as “changes in awareness, knowledge and understanding, ideas, attitudes and perceptions, and policy and practice as a result of research” (Morton, 2015, p. 406), and it is guiding university and municipal strategic plans and funding body directives in many countries (e.g., Australian Research Council, 2022; REF, 2021; SSHRC, 2019).

Library and information science (LIS) professionals are entrenched in knowledge translation, mobilization and exchange activities, or what Shaxson et al. (2012) have coined “K*.” This may be most readily observed in scholarly communication and publishing. Librarians interpret and negotiate copyright laws, develop and maintain publishing infrastructures, e.g., institutional repositories, and lead open education initiatives to facilitate access to materials (Burpee & Fernandez, 2014). However, the current emphasis on research impact may mean new roles and responsibilities for LIS professionals. Given et al. (2015) proposed that academic librarians could further support research impact within university settings by aiding researchers in the use of altmetrics, creating accessible translations of scholarly works, and reaching non-academic audiences through new publication venues. In more recent work, we applied Shaxson et al.’s (2012) K* Spectrum Model to three case studies involving librarians and literacy educators working in community and academic settings (O’Brien et al., 2022). The K* Spectrum Model highlights information functions (e.g., making information available and usable), relational functions (e.g., facilitating dialogue amongst diverse constituents), and systems functions (e.g., changing or designing elements in the environment to encourage information sharing), along with the people who support these functions. The model distinguishes information intermediaries, knowledge translators, knowledge brokers, and innovation brokers based on the extent to which they inform versus collaborate with communities, and whether community members are viewed as “knowledge users” or “co-producers.” Although LIS professionals may be more commonly referred to as information intermediaries, we illustrated how they occupy all roles and fulfill all functions in the K* Spectrum, dynamically responding to changes in the local context (O’Brien et al., 2022).

As part of an ongoing project called STOREE (Supporting Transparent and Open Research Engagement and Exchange), we have been gaining an understanding of the current landscape for information professionals with respect to KE. We adopt the term “knowledge exchange” (KE) (rather than translation or mobilization) in this project because “exchange” implies bi-directional communication between researchers and knowledge users (LSE, 2023), and acknowledges that communities create and curate their own knowledge products and sources of expertise (UBC Learning Exchange, 2020). We interviewed 24 information professionals working in varied academic, public,
and non-profit settings about their KE activities. Of specific interest to us was not only how LIS professionals were engaging in this work, but how they were reflecting on it and documenting it within their organizations and communities. In this paper, we share key findings from these interviews related to assessing and evaluating KE, including participants’ challenges with existing LIS assessment and evaluation methods and frameworks, the difficulty of showing value for KE work, and the desire for alternative, more dynamic assessment methods. We discuss these findings with respect to previous research in LIS and KE more broadly to consider professional and organizational implications.

LITERATURE REVIEW

With some exceptions, little research has explored the professional development needs, opportunities and challenges of LIS professionals engaged explicitly in knowledge translation, mobilization and exchange work outside of scholarly communication and publishing (Hall & Ryan, 2021; Van der Graaf et al., 2018). We see this as a fruitful area of inquiry given the potential for LIS professionals to contribute to research impact efforts (Given et al., 2015) and to use KE frameworks to provide a holistic understanding of community-based projects (O’Brien et al., 2022). LIS professionals’ roles in KE – both how they support it and how they engage in it in practice – are connected to the ability to document this type of work and the value placed upon it. In this review of related literature, we examine library assessment and evaluation to provide context for the importance of documentation and valuation.

Library assessment and evaluation

Library assessment pertains to “ongoing improvement of the collection, space, or service” (Connaway et al., 2017, p. 10); evaluation is the accumulation of assessment activities, tools and methods. Evaluation frameworks may be derived from professional associations (e.g., ACRL’s Benchmark: Library Metrics and Trends) or parent institutions (Nitecki et al., 2015). These frameworks help monitor progress towards goals and objectives over time (Connaway et al., 2017) through stated outputs, outcomes, and impacts. Outputs are tangibles that can be produced or delivered, such as publications and reports, and result in outcomes (Kelly & McNicoll, 2011). Outcomes are short- and long-term changes that may be objective, e.g., enhancements to a system, procedure, or policy; subjective, e.g., increased satisfaction and awareness or relationship development; and learning related, e.g., knowledge creation or skills development (Plummer et al., 2020; 2021). Outcomes should lead to impacts, which as “broader and longer-term community and societal changes” (Nelson, 2019, p. 13).

Library assessment work is carried out for two fundamental purposes: “improving” the library (e.g., understanding users’ needs and behaviors, making decisions), and “proving” the library (e.g., advocating for resources, showing accountability, responding to administrative requests or economic and political realities, and demonstrating benefits to constituents and parent institutions) (Doucette, 2016, p. 291). Some argue that the need to both “prove” and “improve” libraries has created a reductionist culture (Urquhart, 2018), where “assessment is the golden bullet that when ‘done’ will achieve evidence, directions, and judgment” (Nitecki et al., 2015, p. 207). Nitecki et al. (2015) contrast this approach with “effective assessment” that leads to meaningful outcomes and impact, arguing that there is currently a disconnect between current practice and “what is desired (i.e., evidence of impact, directions for program improvement, judgment of value)” (p. 207).

Impact comes from showing the effects of library services on individuals’ and communities’ experiences, rather than looking solely at quantitative data (e.g., general patron satisfaction obtained through a survey, number of article downloads from a database) (Oakleaf, 2013). Farell and Mastel (2016) agree, saying that quantitative metrics “tell a portion of the story of libraries’ impact, [but] they do not tell the whole story” (Introduction, para 2). There may be general agreement that multiple (quantitative and qualitative) methods of inquiry are necessary to understand the impact of services and programs over time; however, lack of familiarity with some kinds of data collection approaches may be a barrier for engaging in holistic assessment. Farell and Mastel (2016) surveyed 39 librarians and found that, while the majority were comfortable with quantitative approaches, such as counting the number of people using a space or attending an event, fewer were comfortable with qualitative methods, including interviews and focus groups. Further, community engagement activities may be viewed by as “marketing activities” or part of the “dailyness” of library outreach work (Polger & Okamoto, 2013). As such, they may be disconnected from the mission, goals and objectives of the parent institution, and therefore not captured as contributing value using existing assessment and evaluation frameworks (Farrell & Mastel, 2016).

Demonstrating value

Value has been described in myriad ways, including cultural, educational and financial (Kelly & McNicoll, 2011; Matthews, 2019). The library’s value may be appraised in terms of its collection, e.g., size, scope; the extent to which library resources are used, e.g., number of items circulated; constituents’ attitudes toward the library, e.g., user satisfaction surveys; or its ability to support the desired outcomes of the parent institutions, e.g., student success (Connaway et al., 2017). Value is traditionally thought of in economic terms, where the cost of operating library spaces and services is weighed against the benefits to library users (Missingham, 2021). Economic value is linked
with narratives of accountability and return on investment (ROI) (Missingham, 2021; Nicholson, 2015). For instance, the LibQUAL+ survey, used to assess the quality of academic library facilities, services and resources, may encourage an “audit culture” that treats library patrons as “consumers,” and lacks the ability to show true impact (Urquhart, 2018, p. 122). Further, Clarke et al. (2022) argue that economic value calculations do not account for the invisible labor of library staff.

It has been suggested that the commodification of libraries should be dismissed in favor of social value, which focuses on the significance of libraries to constituents and communities (Missingham, 2021). Social value could result in “transformative” learning experiences for university students (Nicholson, 2015, p. 334), improved social cohesion, enhanced self-efficacy, increased intellectual or social capital, etc. (Matthews, 2019). However, social value outcomes are less tangible, and their collection and use may be disconnected from the transactional, quantitative data typically collected by libraries (Oakleaf, 2010). It has been argued that using qualitative and quantitative metrics in tandem can be used to demonstrate social value (Missingham, 2021). The discourse around KE and research impact may support greater incorporation of social value into library assessment and evaluation.

Research impact recognizes that societal issues do not operate in closed systems where direct cause and effect relationships can be observed between activities and outcomes (Morton, 2021); evaluation is longitudinal; and any change that occurs may have multiple contributing factors, including, but not limited to, a single input like a research study (Morton, 2015). It has been pointed out that “[t]here is little research on how library services lead to value generation in the lives of library users and ultimately in the community itself” (Matthews, 2019, p. 121). Thus, the ability to better capture social value may have implications for how the work of information professionals is prioritized and validated from both institutional and societal points of view.

**The current study**

In Canada, where our research is situated, university strategic plans continue to highlight teaching excellence and research innovation, but also call for diversity and decolonization, local and global community development and sustainability, and public discourse and knowledge exchange (e.g., University of British Columbia, n.d.; York University, 2020). Similarly, cities are including environment and climate, social development, and equity commitments in their long-term planning processes (e.g., City of Toronto, 2023). A recent examination of Canadian and US public library mission statements revealed that, in addition to being places for communities to access multimodal materials that meet their needs, libraries seek to “connect and empower citizens,” provide equitable access to information, and be sites of “transformation” and “enrichment” (Fraser-Arnott, 2021, p. 244). These themes reflect memory institutions’ alignment with the kinds of aforementioned priorities identified by universities and municipalities. Further, some scholars have petitioned for more critical reflection of assessment work (Magnus et al., 2019) and questioned how the “values of the library or librarianship fit into that process” (Doucette, 2016, p. 289). The current study picks up these threads with respect to how library assessment and evaluation are currently practiced, discussed, and being reimagined, and positions this against a backdrop of institutional and societal shifts toward mobilizing knowledge for individual and community impact. In doing so, we demonstrate how the ongoing KE work of information professionals can be supported by interdisciplinary frameworks that advocate for longitudinal, mixed methods approaches. The research questions guiding our inquiry are:

1. (How) are information professionals engaged in knowledge exchange evaluating and assessing their work?
2. What characteristics of KE-related work are being captured by existing evaluation and assessment practices, and what gaps have participants identified?

**METHODS**

**Recruitment and participants**

This study received ethics approval from the Behavioral Research Ethics Board at the University of British Columbia, Vancouver, BC. Information professionals with a Master of Library and Information Studies (MLIS) or equivalent degree were recruited through email listservs of local and national library and archival associations and a national knowledge exchange network between January-May 2020. The goal was to reach LIS professionals working in a range of organizations and roles and learn about the ways in which they were engaging in knowledge exchange (KE) practices. KE was defined broadly in the recruitment notice as:

…the ways in which information professionals help to translate, share, and move information within and between the communities they serve. Information professionals might engage in this work as part of a research team, in relation to open access and scholarly communication initiatives, supporting community archives, adopting or facilitating community-led strategies in the development of library services and programs, connecting libraries and the public in ways that lead to knowledge exchange, and so on.
Interviews were conducted with 25 people. All participants selected a pseudonym for the study to preserve their anonymity. One person withdrew from the study post-interview and the researchers deleted all audio and text-based files associated with their participation.

The remaining 24 participants had a range of professional experience, from one to 25+ years (Mean = 11.5 years). They worked in academic libraries (n=13), non-library university settings (n=4), public libraries (n=3), non-governmental organizations (NGO) and associations (n=2), community archives (n=1), and hospitals (n=1). All participants were fluent in English and interviews were conducted in English. The majority (n=23) of interviewees identified as female. Interviewees resided in one of three Canadian provinces (Alberta, British Columbia, and Ontario), with the majority based in BC (n=17). Participants self-described their areas of professional specialization as encompassing the following areas: community engagement (n=5), medicine and public health (n=4), archives and special collections (n=5), information and public services, including discipline specific liaison work (n=3), open education (n=2), community archives (n=1), knowledge mobilization and research impact (n=2), Indigenous knowledge systems and engagement (n=1), and embedded research facilitation (n=1).

Procedure
The recruitment notice included the researchers’ email contact information. People who were interested in the study reached out to the researchers and were sent the consent form via email for further information. For those who wished to take part, a mutually convenient time was arranged for the interview to take place. The timing of the study coincided with the Covid-19 pandemic, and therefore all interviews – except one that occurred pre-Covid lockdown – were conducted remotely via the telephone or video conferencing software. Participants were asked to read and return a signed copy of the consent form prior to the interview; however, at the beginning of each interview we reviewed the consent form and offered to address any outstanding questions or concerns. Next, participants were asked semi-structured interview questions related to:

- Professional experience, including education, years of professional experience, areas of interest or specializations, and a general description of their workplace, e.g., “large academic library.”
- Examples of knowledge exchange initiatives and projects in which they had been involved, as well as strengths they, as information professionals, brought to this work, and any experienced challenges.
- Reflection on KE competencies with respect to their importance in their work; for example, ability to understand the organizational context and research process, collaborate and co-create knowledge with constituents, and engage in knowledge translation, dissemination and exchange processes and activities.
- Personal and professional opportunities to develop KE competencies, skills, attitudes and expertise, and the potential for working with other individuals and units on knowledge exchange projects.
- Reflections on what is needed for LIS professionals to be successful in KE work.

All interviews lasted approximately 60 minutes. At the conclusion of each interview, participants were thanked for their time and given a chance to ask additional questions about the study. They received a follow-up email with a debriefing form and an electronic gift card valued at $20 CDN.

Audio recordings of interviews were transcribed by members of the research team or a professional transcription service. Author KM reviewed the written transcripts, making some corrections to sections where the audio files had been unclear and caused transcription errors. The corrected interviews were sent to individual participants, who were given an opportunity to review, amend and redact their content. As previously mentioned (“Recruitment and participants”), one person withdrew at this stage, leave 24 transcripts for analysis.

Data analysis
NVivo software was used to support qualitative data analysis. This research used codebook thematic analysis (TA), which used some pre-determined themes and a structured codebook, but allowed for open-ended, organic coding and analytic theme development (Braun, Clarke, Hayfield & Terry, 2019). Codebook TA allowed us to work as a team on data analysis. This enabled us to maintain some structure in the coding process while being open to emergent ideas (Clarke & Braun, 2014).

Our process was both deductive in inductive. Authors HO and KM first independently read through a selection of transcripts and made notes about our observations. We then came together to share our initial impressions and observations. The semi-structured interview questions guided the topics participants discussed with us, but exploring topics from participants’ perspectives brought new and deeper insights. For example, while we anticipated evaluation and assessment would be a thread in the interviews based on our interview questions, participants went beyond describing their current evaluation and assessment practices. Specifically, and without prompting, they spoke about challenges in their practices, including the difficulty in documenting intangible outcomes in their work.
Next, we developed tentative research questions related to evaluation and assessment and moved into generating codes (Clarke & Braun, 2014). The codebook was developed iteratively by authors HO and JY, with JY taking the lead on coding. The codebook contained definitions for each code and examples from the data to illustrate the code. During this process, we reviewed the codes for clarification and expansion, and the codebook was revised accordingly. For example, the code “challenges” was made more granular to include types of challenges, e.g., staff capacity, project duration, staff knowledge and expertise, etc.

We examined the codes and their categories to begin to develop themes. These included a description of challenges with current assessment and evaluation approaches, tensions between what was currently being done and what interviewees wanted to do, or felt would be more meaningful to do, and how the assessment and evaluation space could evolve. These “prototype” themes were revised and refined to look at the alignment of coded data within themes and in relation to other themes (Braun et al. 2019). Finally, the themes were revisited with respect to the initial research questions and the reviewed literature and are presented below as “Challenges with existing assessment and evaluation approaches,” “Showing the value of KE-related work,” and “Doing evaluation differently.”

FINDINGS
Interviewees described the use of multiple methods in their own practice and workplaces. Much of what they shared aligns with library assessment and evaluation at a general level. For example, they discussed gathering and maintaining statistics for: numbers of interactions, consultations, and people attending events and workshops; resource adoption rates; web and social media analytics; open rates on newsletters and emails; database vendor supplied statistics; and user surveys. Qualitative data was also mentioned, including verbal and written feedback from constituents. These verbal or written accounts often described the significance of a service or program; one interviewee referred to them as “impact stories” (“Lindsey,” Public Library).

Quantitative data was gathered through formal channels. For example, using feedback forms at events to gather input from attendees or surveys and focus groups to evaluate program outcomes. One interviewee’s organization implemented a micro survey tool into their website to capture quick feedback about specific digital resources (“Nina,” NGO). Qualitative data was typically captured informally. A few people mentioned receiving unsolicited feedback through emails (e.g., “Ann,” Community Archives) or noting when resources they had created were used and adapted by others (e.g., “Fiona,” Academic Librarian). However, some interviewees engaged in conscious documentation efforts, such taking photos at events and sharing these via social media (“Dana,” Academic Library; “Lisa,” Academic Library) or archiving materials from events (“Tara,” Archivist).

When it came to discussing current methods and tools, participants shared challenges on multiple levels. First, existing library assessment and evaluation models and methods were inadequate for capturing the nuances of relational KE-related work (Theme 1). As a result, participants experienced a disconnect in terms of how they were expected to document and evaluate their work, and what they truly wished to capture (Theme 2). In the following sections, we elaborate on these challenges and tensions, along with some of the personal and organizational barriers to “doing things differently” in this space (Theme 3).

Challenges with existing assessment and evaluation approaches
A few participants recognized that quantitative data was easy to collect and could provide a snapshot of the reach of a program, service or event, or evidence for decision making. For example, “Nina” (NGO) gave an example of a client asking her to discontinue a current awareness service during the Covid-19 pandemic due to their experience of information overload. She examined the email open rates to confirm that this service was still being used by the majority of clients. In this case, the quantitative data enabled “Nina” to decide to continue the service. Quantitative data, such as gate counts and website page views, is collected unobtrusively, making it concrete, convenient, and less onerous on clients to provide feedback. “Lindsey” indicated that quantitative metrics were informing the strategic plan at their public library for these reasons.

However, participants pointed out the limitations of quantitative data for KE-related activities in particular. “Dana” (Academic Library) summed this up, saying, “you can’t assess community engagement in the same way you can assess other programs and initiatives within libraries.” Dana and others argued that quantitative metrics did not reflect the multiple and myriad ways people interacted with their organizations, nor the impact of their services on community constituents. Academic librarian “Sarah” spoke of the “different kind of understanding” that comes from interpreting quantitative data, e.g., newsletter open rates, compared to “more in-person, more in-depth, higher-touch activities” that enable LIS professionals to understand the people with whom they are engaging.

Interviewees underscored the relational work of community engagement and knowledge exchange and that it was necessary to consider the temporal elements of such work. “Lisa,” whose work was situated with Indigenous communities, felt that the information professional’s role was one of facilitation and connection:
But the value of – the KE that can then happen in the community among Elders and younger generations because of the preceding steps of KE in the profession — we’re an important part of the exchange for cultural revitalization work, but the most important part is with the community. And recognizing our place in that conversation is a very important part of the relationship. Having that respect for our relationship and our place in that relationship, I think that we have to be humble and share what we know while recognizing that the reason we are doing this is so they can take the reins and share the knowledge that they need to share themselves, and decide whether it gets shared more broadly (“Lisa,” Academic Library).

Lisa’s example emphasizes building and maintaining relationships, and supporting communities to make decisions about what happens to the knowledge generated from their collaborations. Community self-sovereignty affects the extent to which LIS professionals may be able to report on the outcomes of community-based initiatives, and how best to do so, which may be at odds with typical assessment and evaluation practices.

Many participants articulated that relationship building takes time and care, and the process may not result in tangible outputs and outcomes. “Lindsey” described their approach to cultivating and maintaining relationships:

“I’d say in terms of trying to make time for it, again I just come back to setting specific goals on the workplan. I have check-in dates where I work to check in with various members of the community just to see how they’re doing, and we’ll go out for a coffee. Almost in the same way I approach a lot of relationships in my life that I see as important, but I know can kind of slip out of my daily purview. If I care about this aunt or if I recognize that this friendship is important to me and our lives don’t crisscross on a regular basis, how do I keep those going? Well, you have to make that time for it…” (Lindsey, Public Library).

These kinds of informal check-ins may be just as impactful as formal programming and services, but may not be viewed as significant or indeed be “counted” as part of one’s work. As Archivist “Tara” astutely asked, “how do you measure a relationship?”

A few interviewees shared that project goals shifted over time due to the learning that took place within the project and changes in the broader environment. As a result, indicators identified at the beginning of a project may be less applicable later on, and other data may not have been collected initially that would later be useful (“Amanda,” Academic Librarian); understanding whether services and programs were truly impactful may not be evident until three-five years had passed (“Alice,” University Knowledge Mobilization Unit); this timeframe was not in alignment with research grant funding cycles and, in the case of one interviewee, the completion of their formal role coordinating a project with industry partners (“Carol,” Academic Library). For these reasons, library strategic plans may be limited by taking a short-term view: “I mean you put something in your strat[egetic] plan and it’s your four-year strat[egic] plan. Do you take it off at the end of those four years?” (“Lindsey,” Public Library). The long-term nature of KE-related work warrants consideration of the sustainability of community-based initiatives and the fate of relationships when funding dries up, strategic plans change, and information professionals are assigned to new projects or in precarious employment situations (e.g., contract work).

**Showing the value of KE-related work**

Although participants agreed that quantitative methods do not adequately capture the impact of their work, they were required to collect and report on statistics. This revealed a disconnect between what interviewees were evaluating versus what they most cared about or wanted to evaluate.

A few interviewees said there was an emphasis on “numbers” (e.g., partnerships, new funding) in how their units were evaluated. “Alyssa,” a research facilitator, spoke to the challenge of trying to show the value of qualitative outcomes, such as network and relationship building, when reporting to funders in an academic environment where “papers published and conferences attended” were most prized. They described their reporting process as “kind of like checking boxes,” where the relational work was “harder to quantify and to justify as being worth the funding that we get but, in my opinion, [is] even more important than publication counts or citation counts” (“Alyssa,” University; embedded in research team).

In contrast, the practice of gathering, sharing and reflecting upon stories was highly valued by interviewees. The use of stories was motivated by the desire to learn about the impact of services and programs on communities over time. “Lindsey” (Public Library) viewed impact stories as a powerful expression of “trust and goodwill” when shared by constituents. Some interviewees took an active role in trying to document relational work with communities to demonstrate its value within their institution, as “Tara’s” example illustrates:

What we try to do is…report on the collaborations we’ve worked on. For example, we were asked to -- because of a relationship with a particular First Nations community, because of the trust that’s been established and the longstanding relationship that’s evolved -- we were asked to assist with the return of
regalia to the community. And reporting on all the joint workshops we’ve given across communities or the meetings we’ve attended across communities…reporting on those things, joint exhibits, internships, just whatever we can to show that these relationships bear fruit, in whatever way you can show (Tara, Archives).

Overall, gathering evidence to show value for one’s work was a strong thread in the interviews. Many participants expressed the value of stories as a way to “keep building the case” for their work (“Sarah,” Academic Library), and, in some cases, these narratives were incorporated into formal reporting mechanisms. This was especially important when a program or service did not have consistent funding, or when the numbers of people served by a program or service was low. “Alex” (Public Librarian) and “Dana” (Academic Librarian), for example, gave examples where the numbers of people served by an initiative was low, but the actual impact was significant for individual community members. In addition, “Laura” described a number of community-based partnerships as part of an ongoing effort to enhance their institution’s reputation, where the goal was to:

try to extend our physical collections beyond our physical walls and display these materials to members of the local public…reinforcing the message that we don’t just exist for the community of faculty, staff, and students -- we are a public university; therefore, these collections belong to the public and really trying to message that in new and different ways over the past five or so years (“Laura,” Archives).

Several people spoke to feeling supported in KE-related work in their organizations by administrators at different levels. At the same time, one person who said they felt supported also mentioned the constant battle to demonstrate the relevance and value of their work (“Kate,” College Librarian). In addition, “Lisa” indicated that, even when they did gather information for evaluation purposes, lack of uptake within their organization was problematic. She said, “It’s difficult for us to ask people to take time out of their day to contribute to a report that is necessary for us to demonstrate that value but it’s not even a report that always gets read” (“Lisa,” Academic Library). This observation reflects that LIS professionals risk overburdening their constituents when they engage in evaluation activities; the lack of acknowledgement and reciprocity in response to investments from communities could perpetuate narratives of extraction in community-institutional interactions.

**Doing evaluation differently**

Interviewees described working as part of committees on community-based projects, working alongside communications professionals in their organizations, creating specific professional positions for assessment and evaluation, and forming committees within their organizations to determine what data to collect and how to report on activities and outcomes. However, some of these ambitions were not yet at the implementation stage. In one interviewee’s case, the ability to evaluate program outcomes was possible because external funding allowed them to hire contractual research staff specifically for this purpose (“Sarah,” Academic Librarian). Thus, KE-related work and its evaluation may be viewed as important by interviewees and their organizations, but was largely at a nascent stage at the time the study took place.

One of the reasons for this may be that information professionals have limited capacity for evaluation in their current roles. Several participants relayed it was challenging to do the work, let alone evaluate and advocate for it. “Alex” (Public Library) said that their organization was trying to build evaluation into various positions, but this was “very exhausting. It takes a lot of time.” Time was lacking for individual participants, but also their organizations. “Lindsey” (Public Library) indicated that their workplace was, “in a state right now as an organization where we need to do some evaluation around what do we keeping doing and what do we let go of,” demonstrating the need to pause, reflect on, and reorient current practices.

In addition to limited time, interviewees expressed that knowing how to evaluate KE-related work was difficult given its intangible, relational elements. “Caitlin” (Academic Librarian) indicated that their institution was strategizing how to “measure knowledge exchange on our campus” but spoke to the limitations of the “bibliometrics-based” approach it was currently taking. As a result they admitted, “we want to support knowledge exchange, but we’re not exactly sure how to do that.” “Caitlin” was not the only person who was struggling with how to go forward. “Alex” (Public Librarian) shared that the question of how to engage in evaluation was much discussed in a community-engaged interest group in which they participated, but no clear directions had yet emerged. Others underscored the need for more dynamic assessment that featured both formal and informal practices, but they also felt constrained by project-limited funding and timelines (e.g., “Carol,” Academic Librarian).

“Amanda” (Academic Librarian), who described the “disconnect” between current evaluation models and efforts and emerging areas of work, including community engagement, relationship building, and accountability in long-term projects, suggested that it might be necessary to look “outside of our profession” for solutions. “Amanda” specifically highlighted models of knowledge mobilization and exchange, and “Alice” (University, Knowledge Mobilization Unit) emphasized the need to go to constituents or partners to understand impact: “So ‘Has there been
a policy change? Has there been a service improvement? What’s the story there?’ that’s what we try to get people to think about.”

“Dana” (Academic Library) pointed out that LIS roles involving knowledge exchange constituted “such unique positions” and they desired “some sort of network, or community…even a community of practice of people doing similar work.” “Dana” also asked whether “there are other knowledge exchange or knowledge mobilization tools that I should be learning, that I should be incorporating into my practice?” and had not come across any such resources. In addition to the need for support at the institutional and professional levels, “Lindsey” (Public Library) raised the need to make the work of LIS professionals in knowledge exchange more visible to illustrate “what libraries are doing to fill in the gaps when different services are cut.”

**DISCUSSION**

Participants in our study reported a number of quantitative and qualitative methods in use in their organizations. Quantitative approaches were more formalized, while qualitative strategies tended to be more emergent and informal. Our interviewees revealed challenges with existing approaches to evaluation and assessment, felt an impetus to show value or “build the case” for KE work, and expressed a desire to do things differently.

The LIS professionals we spoke with saw benefits to collecting quantitative data (e.g., convenient, non-obtrusive), but did not feel it provided a holistic picture of KE work. Specifically, existing evaluation frameworks did not support longitudinal projects with shifting goals or contexts, and did not legitimize time spent building and maintaining relationships with communities. This may be because service delivery is unique in different settings, and standardized evaluation frameworks may not map to diverse community settings and needs (Matthews, 2019). Magnus et al. (2019), explain that “desire to do useful, actionable assessment work compels us to focus on questions with clearly articulated answers, on activities by which we can easily measure ‘use’ or ‘impact’” (p. 600), but that this approach may be at odds with exploring complex issues. Interviewee “Lisa’s” (Academic Librarian) comments about allowing communities to “take the reins” reinforces that communities should be able to establish their own goals and priorities and determine what outcomes are shared from a collaboration (if any) (Nathan et al., 2017). Thus, in some ways, the process of assessing and evaluating may be antithetical to some aspects of community-based KE. There may be a mismatch in the kinds of outputs, outcomes and impacts that are important to different communities; transactional activities may be viewed more as “box checking” by communities, and LIS professionals themselves may desire deeper, more relational engagement.

Interviewees were aware of the tension between quantitative and qualitative modes of assessment. Some described working in environments that prized quantification (e.g., publication counts, gate counts) and struggling to articulate qualitative outcomes, even though they believed they were more important for conveying impact. Stories were frequently mentioned as tools for personal reflection, and as ways to understand the value of their projects and institutions in the lives of constituents. Some were actively documenting stories they received verbally and via email, creating stories for social media, and collecting photos and artifacts from events.

Yet, Magnus et al. (2018) contend that it is “not just ‘other forms of assessment’ that might be valuable” (“Critiques and Responses,” paragraph 4), but the acknowledgement of “assessment as a social and political act” (“Critical Assessment, paragraph 2). Study participants wanted to do assessment and evaluation differently, but encountered barriers. For busy professionals, assessment and evaluation is a time-consuming activity that leaves less time for doing the work. Clarke et al. (2022), who investigated the labor practices of academic librarians, found that many respondents in their study completed impact reports outside of paid work hours. They argued that this kind of invisible labor is linked to economic valuations that treat the library “as a passive object to be used” and “homogenize” librarians’ labor (Clarke et al., 2022, p. 938). Operating in such a model means that some kinds of labor may be “counted,” while other forms are discounted.

Nitecki et al. (2015) caution that assessment that does not encompass professional values, e.g., lifelong learning, knowledge preservation, access to information, “may run the risk of hindering the evolution of the library’s most powerful values” (p. 203). Different systems may need to be put in place before LIS professionals can engage in more authentic assessment of community-based KE. This may require dramatic organization-level changes in service delivery and redefining professionals’ roles and responsibilities in order to align evaluation with community engagement, advocacy, and collaboration priorities (Kendrick et al., 2023).

**Implications and recommendations**

Some interviewees expressed not knowing where to go to learn about knowledge exchange and its assessment and evaluation, and that being in unique positions in their organizations made it difficult to find support from others engaged in similar work. Next, we consider support at the individual and organizational levels, drawing upon previous research in LIS and implementation science. We return to the idea that knowledge translation,
mobilization, and exchange may offer useful contributions to LIS, specifically with respect to documentation and valuation.

**Individual**

Existing library assessment and evaluation scholarship critiques existing assessment and evaluation frameworks and culture, including the emphasis on economic value, and calls for greater reflexivity with respect to what is measured and how it is measured. Magnus et al. (2019) pose a series of questions to deconstruct the assessment process by centering considerations of power, privilege, and consultation. They write,

> It is precisely through stepping back and questioning the way we have always done things that we begin to consider the ways in which our work has the potential to uphold inequities—in the questions we ask, the populations we survey, and the analyses we conduct (Magnus et al., 2019, pp. 602-603).

The practice of critical reflection or “stepping back” is useful for recognizing the relationship between positionality and practice. It is also aligned with the desire to achieve more socially minded assessment outcomes (Magnus et al., 2018) that align with the KE projects our interviewees described.

Research evaluation typically features well-defined participants, timeframes, and levels of participant involvement, along with the ability to link actions and outcomes (Bonaccorsi, et al., 2020). However, when it comes to societal impact, such attributions are not possible; we can only show how a study, service or program has made a contribution, recognizing that other contributing factors may also be at play (Mayne, 2001).

> The library and other partners in the community identify pressing concerns within the community, and every partner works on improving that topic be it unemployment, kindergarten readiness, and so forth. Community indicators are used to track the cumulative impact of every organization focused on a specific concern over time. Clearly, the public library cannot claim that it is solely responsible for reducing the unemployment rate, but it can claim some credit along with the other partners (Matthews, 2019 p. 122, emphasis added).

Though not attributed as such, Matthews (2019) alludes to the concept of contribution analysis for helping LIS professionals make a stronger case for their role in societal impact. Building a “contribution story” (Morton, 2015, p. 412) involves strategies such as capturing the context, documenting service or program goals and decision-making frameworks, and describing activities, outputs, and observed outcomes (Mayne, 2001). The idea of the contribution story aligns with what our interviewees referred to as impact stories and current LIS research applying storytelling methodologies to digital literacy initiatives and information experience (LaRose & Detlor, 2021; McDowell, 2021). This line of inquiry has the potential to introduce robustness to practitioners’ current story documentation practices.

> We recommend that professional development opportunities, such as online toolkits, videos, and workshops, support LIS professionals in cultivating reflexivity and storytelling practices, and that stories are recognized as legitimate ways for information workers and organizations to document contributions that lead to societal impact.

**Organizational**

Assessment is not only the purview of individuals, but the organizations within which they work. LIS organizations are embedded in systems where decisions are made by university administrators, governments, accrediting bodies, and so on; these external stakeholders influence what memory institutions must “prove” (Doucette, 2016). Theoretical frameworks within implementation science may hold promise for application in LIS institutions. We briefly describe two: Morton’s Pathway to Impact and Ozanne et al.’s Relational Engagement models.

Morton’s (2015) “Pathway to Impact” model is comprised of three stages: research uptake, research use, and research impact (p. 411), and advocates for the use of multiple methods, including self-reports, observations, population statistics, and policy analysis. Research uptake involves creating opportunities for specific users to engage in research. The results of these activities are appraised in terms of research use, i.e., research users’ awareness and capacity to utilize research, and changes in their knowledge, skills, behaviors and practices. Outcomes and contributions are assessed as part of understanding research impact. Building on Morton’s model, Ozanne et al.’s (2017) “Relational Engagement” model proposes three additional elements: productive interactions, enhanced capacity, and improved social networks. Productive interactions are multidirectional exchanges between researchers and constituents; research users and researchers both enhance their capacity through collaborative projects, e.g., increased knowledge, new skills. This component is particularly interesting for reinforcing reflexivity amongst LIS professionals, where lessons learned can be actively applied in future practice. Finally, social networks include new contacts and improved knowledge flows, but also take into account trust and community building. The Relational Engagement model attempts to make the intangible more concrete by recommending quantitative and qualitative metrics and gathering evidence from indicators inside and outside the organization. Considering a wider range of assessment activities would be useful for LIS organizations and would justify activities that may not
currently be considered part of assessment and evaluation frameworks, i.e., checking in with partners over coffee or attending a community event as part of relationship building.

*We recommend exploring ways in which research impact models can be adapted to the LIS context to support the development of assessment and evaluation frameworks that champion demonstrating social value and impact.*

**Limitations**

In reviewing the literature about research impact, including university-community engagement, we observed that the scope of activities and assessment benchmarks is wide, many diverse internal (e.g., students) and external (e.g., local community organizations) stakeholders are discussed (e.g., Nelson, 2019), and there are challenges in terms of how to define research impact and what tools and strategies to employ to demonstrate it (Given et al., 2015). Thus, while we see promise in drawing from other disciplines including implementation science for LIS, we acknowledge that work in this space continues to unfold and solidify, and this will affect the ways in which LIS is able to apply it. In putting forward our recommendations, we also recognize that the systems in which our participants and other LIS professionals operate within are complex and entrenched, and making changes to such systems is not straightforward.

**CONCLUSION**

This paper reported on interviews with 24 information professionals about the ways in which they and their organizations assessed knowledge exchange activities. Participants described a range of quantitative and qualitative methods in use in their organizations. They expressed that traditional, quantitative metrics failed to capture the relational, holistic nature of KE, while qualitative metrics were favored but less formalized and legitimized. Our participants identified gaps in current assessment and evaluation frameworks with respect to KE work, including a mismatch between what they wanted to capture and what current tools and methods enabled them to capture, and incongruence between the timescales of community-based projects and organizational strategic plans and mandates. They also identified resource constraints that challenged their ability to practice meaningful assessment of KE, along with the need for more flexible evaluation frameworks. We discussed these findings in relation to prior research, but also drew upon ideas and models from implementation science to make recommendations for supporting information professionals in the many roles they occupy in the K* Spectrum.

LIS professionals have unique and valid perspectives on KE-related work. Our participants understood the kind of information they needed to demonstrate success when it came to mobilizing knowledge and supporting positive outcomes in their communities. Yet, they did not have an effective evaluation framework to shape and justify the collection of this information, and they knew it did not do the work justice to compress it to fit within the standard metrics or reporting mechanisms. This paper gives voice to these challenges and proposes some future directions to help shift library assessment and evaluation toward the kinds of social impacts our participants aspired to achieve.

**ACKNOWLEDGMENTS**

This research was supported by Social Sciences and Humanities Partnership Development Grant (FAS F17-05624). Thank you to the participants in this study who shared their time and experiences with us. We are grateful to our grant partners (UBC Learning Exchange, UBC Library, Simon Fraser University Library) and colleagues from the Making Research Accessible Initiative.

ABSTRACT
This paper examines social science and humanity theories that have been applied to studies dealing with misinformation. We identified 273 articles published from 2012 to 2023 from Web of Science, Scopus, and ScienceDirect. These articles are empirical studies that have applied one or more social science or humanity theories. Applying content analysis approach, we identified 124 theories that authors have used in their studies. These theories belong to different disciplines or fields, such as political science, psychology, communication, sociology, and economics. We discuss the top 11 theories and how they have been used to understand misinformation and its impacts. This study provides insights into understanding current misinformation studies and rich resources for information evaluation and information literacy education.

KEYWORDS
Misinformation, theories, systematic review

INTRODUCTION
Current information age makes it convenient to obtain information via all kinds of digital platforms, such as search engines and social media. However, people and society are challenged by the flooding of misinformation, which has become a popular topic of discussion at the recent iConference and ASIS&T annual conferences. Various aspects of misinformation have been raised and investigated by the keynote speakers and the conference participants. Literature shows that information science researchers have been exploring, along with researchers in other disciplines, the spread of misinformation on social media, its impact on different groups of people, and the methods to detect and correct misinformation.

Studies investigating the spread and impact of misinformation apply theories in multiple disciplines to guide the investigation. Nguyen et al. (2023) conducted a content analysis of 151 articles in the library and information science domain. While around 39% of the articles did not use theories, more than 40 theories, models, and frameworks have been applied in these studies. However, their analysis was limited to library and information studies (LIS) journals and did not differentiate theories in social science and humanities from frameworks or models in computer science. The coverage of social science and humanity theories and their disciplines is unclear.

This study aims to achieve the following purposes: (1) to identify social science and humanity theories that have been applied in misinformation research; (2) to understand the disciplines of these theories, and (3) to examine how they were used. The research questions we would like to answer include the following:

RQ1: What theories have been applied to guide misinformation studies?
RQ2: What are the disciplines or fields that these theories belong to?
RQ3: How have these theories been applied in misinformation research?

Our study focuses on social science and humanity theories. Many computational models and frameworks have been adopted to study misinformation detection and correction, which are also part of misinformation research. These types of theories are worth a separate examination for the purpose of improving information systems fighting misinformation, which is out of the scope of this study.

RELATED LITERATURE
Theories and their functions
There is no agreed-upon definition of theory. The word theory originated from the Greek word “theorēin,” meaning “to look at”; “a rational type of abstract thinking about a phenomenon, or the results of such thinking,” (Wikipedia), “to consider, speculate, and look at” (Etymonline, n.d). Among the many definitions of theory, Merriam-Webster Dictionary describes it as “a plausible or scientifically acceptable general principle or body of principles offered to explain phenomena”; Oxford Dictionary defines it as “a supposition or system of ideas intended to explain something, especially one based on general principles independent of the thing to be explained.” Also, a theory is viewed as “a set of statements about the relationship(s) between two or more concepts or constructs” (Jacoby & Jacoby, 2010, p.28), as a model applied to everything and nothing specific (Prokopowicz, 2019), as a set of claims advanced amid continuous abstractions aimed at a generalized statement expected to interpret a phenomenon.
The concept of Misinformation also has different definitions or other names. It is defined as “false information” (Fetzer, 2004), inaccurate information (Karlova & Lee, 2011), as a virus (Spinney, 2019; Smith & Bastian, 2022), and as “articles that are intentionally and verifiably false, and could mislead readers” (Allcott & Gentzkow, 2017) (Nguyen et al., 2023, p. 2). Although misinformation and disinformation are often misunderstood, misused, or even used interchangeably (Allen & Zimmerman, 2022), they are different. However, misinformation, disinformation, rumor, or fake news share the wrong message(s) that can mislead with adverse consequences (Nguyen et al., 2023; Wu et al., 2019) and can be much worse when it relates to health, senior adults, and children. Therefore, this study focuses solely on misinformation as an umbrella term, and the essential characteristics of misinformation include that it is not true and may lead to serious, negative consequences when it is believed or spread.

Various social media platforms are considered the most popular channels for spreading misinformation. These platforms, such as Facebook, Twitter, Instagram, TikTok, and Snapchat, make it easier for people to share information and connect with each other. Unfortunately, people may be misled by misinformation if they do not carefully evaluate messages they receive from these platforms. Research found that there are many factors that may aid the spread of misinformation, such as Altruism, ignorance, peer pressure, and attention-seeking (Apuke & Omar, 2020; Horner et al., 2021). Evidence suggests that misinformation is more likely to be shared, especially when it aligned with people’s pre-existing beliefs (Del Vicario et al., 2016). Health-related and political misinformation tends to spread quickly (Roozenbeek et al., 2019).

Wilson (1977) explores the prevalence of private ignorance and public knowledge in our world, which may help us to understand the misinformation spread. He asserts that the public seems ill-informed, while individuals often possess significant gaps in their understanding. This gap will lead to decisions based on unreliable information. Wilson argues that as long as credible knowledge is not effectively shared with the public, the proliferation of misinformation will persist.

Misinformation could be costly and deadly. For example, health-related misinformation has been a major threat to people’s health during COVID-19 (Roozenbeek et al., 2019). Certain groups of people are vulnerable to misinformation, for example, young adults (Leeder, 2019; Veeriah, 2021) and senior adults (Lee, 2018; Seo et al., 2021). In this study, we used a similarly broad definition as by Nguyen and colleagues (2023) for misinformation: misinformation refers to articles, posts, messages, and other representations that are intentionally fabricated and verifiably false to mislead people.

**Review Studies on Applying Theories in Misinformation**

Misinformation studies have emerged as an important area of research due to their increasing prevalence and potential consequences on people and society. We believe theories are essential to guide empirical misinformation studies and should be explored more, especially in the field of Information Science for fighting misinformation. Unfortunately, we found very few reviews that have been conducted to understand the theories and their applications in misinformation research.

Orr and Gordon (2022) conducted a scoping review on communication and messaging interventions that utilize health behavior theory to address COVID-19 vaccine hesitancy. An exhaustive list of keyword pairings was used to search the articles. The identified 36 articles and analyzed them to answer their research questions. The scoping review identifies several health behavior theories that have been applied in the context of COVID-19 vaccine hesitancy studies, such as the Theory of Planned Behavior, the Health Belief Model, and the Social Cognitive Theory. These theories concentrate on various factors that could influence individuals’ decision-making processes, such as perceived susceptibility, perceived benefits, social norms, etc. The authors concluded that utilizing health behavior theories in communication and messaging interventions holds promise in addressing vaccine hesitancy.
These interventions typically involve tailored messages, persuasive communication, and targeted information delivery. The authors resulted in some vital intervention strategies, such as providing factual information about vaccine safety and efficacy, addressing misconceptions and concerns, utilizing social norms, and emphasizing the collective benefits of vaccination. The writers also emphasized the importance of evaluating the cultural, social, and individual factors that contribute to vaccine hesitancy.

Another study by Tsamakis et al. (2022) reviewed 43 studies of the data and factors associated with COVID-19-related conspiracy theories during the first year of the pandemic. Their systematic review aimed to summarize the existing literature on the topic and identify the main factors contributing to the development and spread of conspiracy theories related to COVID-19. The authors organized the factors into three categories: sociodemographic (age, gender, income, etc.), psychological (pessimism, impulsivity, anger, and many more), and others (political conservatism, religiosity, mistrust in science, fear, panic, social polarization, and more). Their analysis showed that between 0.4% and 82.7% of participants agreed with at least one conspiracy belief. Therefore, the authors suggest that large-scale collaborations between governments and healthcare organizations are needed to curb the spread of conspiracy theories and their adverse consequences.

**RESEARCH DESIGN**

This study utilized a systematic review approach to answer the research questions. The research design process is shown in Figure 1. As illustrated by Figure 1, our study can be divided into three stages: Data collection, Data Selection, Verification, and Analysis. Specifically, we chose three renowned large academic databases (Scopus, ScienceDirect, and Web of Science) to collect metadata and select articles according to several inclusive and exclusive criteria. Then, we performed meta-analyses automatically to understand the characteristics of the data, and conducted manual content analysis to answer the research questions.

**Figure 1. The Research Design**

**Data collection**

To achieve our research purposes, we utilized search terms such as “misinformation,” “theories of misinformation,” “theories,” and “theory” to search for relevant articles. First, we entered the keywords into the topic search fields: Article title, Abstract, and Keywords on Web of Science, Scopus, and ScienceDirect databases. The searches retrieved 1,015 articles on the Web of Science, 1,268 articles on Scopus, and 51 articles on ScienceDirect as of February 08, 2023. There are in total 1,526 articles after we manually removed the duplicates.

We established explicit exclusion and inclusion criteria to further narrow down the dataset. We decided to analyze articles published from 2012 to 2023. Furthermore, these articles needed to be peer-reviewed and written in English. We found 840 articles from the Web of Science, 747 articles on Scopus, and 17 articles on ScienceDirect that met the above requirements. We manually removed the duplicates among these articles, and 876 remained. The metadata records of each article, such as author, article title, venue, publication year, ISSN, URL, DOI, abstract, and author keywords, were used to remove the duplicates.
Data selection and verification
Because this study focused on exploring the application of social science and humanity theories in misinformation, we used the articles' subject field to retain only articles in social science and humanity fields, which led to 489 qualified articles. Furthermore, we manually reviewed each article to finalize the target articles—the inclusion criteria for target articles as in Table 1. Selected articles were empirical studies, full text available, related to misinformation, applied one or more theories, and did not focus on developing computer science or mathematics models. Finally, we downloaded 273 articles, or 55.8% of the 489 articles, as our dataset for analysis and answering the research question.

Table 1. Article Selection Criteria

Meta-analysis and coding
We conducted a bibliometric analysis of the 273 selected articles to understand their general characteristics. Then we focused on identifying theories that have been cited in these articles. Our coding scheme is straightforward: we looked for the following from the articles:

- Theory - A specific theory(s) that is claimed by the author(s) that had guided the research
- Context - The main topic/field or background of the study
- The use of the theory and specifics of the study – How the study used a theory or theories in the research, sample size if applicable, and study context.

After discovering the theories in 273 articles, we searched for several general characteristics, including developer, development time, definition, and discipline, of the top 11 theories.

RESULTS
This section first presents the characteristics of the dataset – the 273 selected articles. Then we focus on the theories applied by these studies, including the list of the theories and examples of how they were applied by the studies.

Characteristics of the selected articles

Paper distribution over time
The final 273 articles were published from 2012 to 2023. Figure 2 shows their distribution over time. The result indicates that 102 articles (37.4%) were published in 2022, followed by 2021 (55 or 20.1%), 2020 (28 or 10.3%), and 2019 (25 or 9.2%). The results are consistent with those by Nguyen et al. (2023). Research on misinformation is still attracting a lot of attention from researchers in different disciplines.
Publication venues
The 273 articles were published in 173 different venues that most of them are academic journals. Table 2 shows the top 11 venues that published the most articles in our dataset. The *Frontiers in Psychology* and *Health Communication* rank first with 10 articles, followed by *Applied Cognitive Psychology* (7) and *Proceedings of the ACM on Human-computer Interaction* (6). Among them, 8 of the journals consider themselves multidiscipline and will accept submissions from different fields. For example, the journal *Information Processing and Management* has been a popular venue for computer science and information science researchers. Also, our dataset includes 3 articles from ASIS&T annual conference proceedings.

Table 2. Top 11 Publication Venues for Selected Articles

Authorship
Our analysis found that most of the papers have 1-4 authors. Specifically, 84 (30.9%) articles were written by 2 authors, 62 (22.8%) by 3 authors, 42 (15.4%) by 4 authors, and 37 (13.6%) by single author.

Theories and their categories
Our analysis identified 124 theories that have been used in the 273 papers. The complete list of the theories we discovered from these articles and their fields can be found from the Appendix 1 of a Google sheet [the link to the Google sheet is provided at the end of the Summary and Conclusion Section]. We are not familiar with some of these theories, so their fields were determined with the aid of search engines and Wikipedia. The fields of the identified theories are summarized in Table 3. The result indicates that most theories are in the field of psychology and its sub areas. Specifically, 27 theories are in Psychology, followed by Communication (18), Social Psychology (13), and Sociology (10).
The number of theories listed in Appendix 1 demonstrates that misinformation researchers have applied a good number of different theories. However, most of the theories were used by just one or two studies in our dataset – the 273 articles. To save time and effort, we decided to focus on the theories that have been used by more than two studies and take a closer look at them. Table 4 lists the top 11 most frequently used theories, their disciplines, frequency (number of papers that used them in our dataset), the creators, and the reference to their initial publications. The Conspiracy theory ranks first with 117 applications, which means this theory was applied by 117 out of the 273 articles, or 42.4%. Other highly applied theories include the Inoculation theory (14), the Fuzzy-trace theory (7), and the Theory of planned behavior (6).

Table 4. Top 11 Common Theories Leading in Misinformation Research

It is interesting to observe from Table 4 that the most frequently applied theories are mainly developed more than 40 years ago. The most applied theory – conspiracy theory, was initially published 160 years ago. Theories developed a
while before the age of social media were applied to explain the infodemic and misinformation. In the next section, we will describe these top 11 theories and their application in some of the articles of our dataset.

**Top 11 common theories leading in misinformation theory research.**

**Conspiracy theory.** A conspiracy is “a secret plan by a group to do something unlawful or harmful” (Oxford Dictionary, n.d.). Conspiracy theory was designed initially to resist fabricated information and reinforced by circular reasoning. But it is now commonly applied to explain a situation that invokes a scheme by certain groups when other reasons are more probable, often seen as politically motivated. This theory has been used in many ways, for example, in our review, Lewandowsky (2021) used it to investigate the rejection of science. Hřčková et al. (2019) used it to deduce the intention of fake news and propaganda. Lewandowsky et al. (2013) applied it to identify the factors underlying the rejection or acceptance of climate science. Nyhan et al. (2016) used it to investigate and test the effects of redactions of government documents on beliefs. And Bolsen, Palm and Kingsland (2020) utilized it to explore social media users’ perceptions and behavior in the context of a pandemic (COVID-19) misinformation.

**Inoculation theory** was initiated to provoke attitudinal resistance against propaganda. It offers an intuitive solution to problems, such as fake news diffusion regarding a viral infection, by suggesting an alternative possibility of a ‘vaccine’ against it. In our dataset, authors utilized this theory in many ways – Roozenbeek & Linden (2019A) used it to develop educational games that can counter the reliance on misinformation and pilot-tested it on 95 randomized fields. Basol et al. (2021) used it to evaluate the efficacy of two pre-bunking interventions to improve individuals’ ability spotting manipulation techniques commonly used in COVID-19. Also, Maertens et al. (2020) applied it to a preregistered extension and replication experiment while exposing subjects to a persuasive misinformation message for a week, then tested whether inoculation effects can protect against a misinformation attack, then examined the efficacy over a certain period.

**Fuzzy-trace theory** proposes that information is encoded on a continuum from precise (verbatim traces) to imprecise representations (fuzzy traces), which generally require more effort to adopt. It helps explain false memory and its development, probability judgments, biases, and fallacies in decision-making. Broniatowski and Reyna (2020) propose and test a model of online media platform users’ decisions to act on and share received information. The model uses factors derived from fuzzy-trace theory to make predictions regarding which content is more likely to be shared. The authors test their model on an existing dataset of tweets about vaccines. Brackmann et al. (2016) recruited 220 participants in the experiment to examine the effects of different types of testing on the vulnerability to misinformation in different age groups based on Fuzzy-trace and Associative-activation theories. Wolfe et al. (2023) used fuzzy-trace theory to guide the assessment of the characteristics of web pages presenting medical misinformation about vaccination that are most likely to affect medical decision-making.

**Theory of planned behavior** maintains that 3 core components, namely, attitude, subjective norms, and perceived behavioral control shape an individual's behavioral intentions. Filkuková et al. (2021) recruited 405 Norwegian participants to examine the impact of individual beliefs on precautionary health behavior, and the results agreed with the theory of planned behavior assumptions. Xiao et al. (2021) based on the theory of planned behavior to explore the relationship between individual trust and experience in fact-checking platforms and their fact-checking behavioral intentions. Alwreikat (2022) applied the Theory of Planned Behavior to investigate 210 Library and Information Science students' behavioral intent to verify the information before sharing it during the COVID-19 pandemic.

**Framing theory** proposes that human thinking is informed by unconscious mental frames triggered by some words or phrases (Gorton, 2016). This theory, on the one hand, can be applied to detect microtargeting. On the other hand, it can be used for misinformation correction, to test theory-based correction messages using loss versus gain framings to combat misinformation online (Facebook), and to investigate online climate change denial and advocacy (Xu & Atkin, 2022). Also, to extend the impacts of correction messages from misperceptions to behavioral intentions and to examine the conditional effects of reflection on information processing. In our dataset, this theory and agenda-setting theory guided Xu and Atkin (2022) in topic modeling of web pages (from 2007-2019) to investigate online climate change denial and advocacy. Likewise, Park, Lee & Jeong (2022) adopted this theory in exploring how the Korean news has framed or attributed the causes of fine dust to internal and external factors. Also, Borah et al. (2022) conducted an experiment guided by this theory to extend the impacts of correction messages from misperceptions to behavioral intentions and examine the conditional effects of reflection on information processing.

**Dual process theory** posits that two systems operate in the human mind - the fast and the slower decision-making process; individuals use both to varying degrees depending on the issue at hand. This story can be used to check propaganda and unfounded rumors (Irenoa, 2021; Nerino, 2021). Irenoa (2021) employed the theory to develop an instrument for purposive sampling and content analysis to understand social media's role in the generation and diffusion of information during the 2015 general elections in Nigeria. Irenoa noted that social media was used to
post offensive information to misinform the citizen against some candidates to sway the election. Furthermore, Nerino (2021) embraced it to explore computational propaganda, a type of political misinformation executed on social networking platforms by automated agents to increase support for a specific political standpoint. To accomplish their goal, the author compared socio-political tweets with the news of the week to check whether the issue addressed by the tweet matched those from the most prominent news media, then to determine the existence of emotional verbiage, emoticons, catchy punctuation, and capital letters. Findings suggest that about 74% attempted to establish a link between the topics, while others may have been misled by these persuasive strategies. It implies that as advocates of democracy and climate action exploit social media to gain support, bad actors can also spread misleading information designed to manipulate users to support a particular cause or leader.

**Protection motivation theory** was initially developed by Rogers in 1975 to help understand human responses to fear appeals and expanded in 1983 to a more general persuasive communication theory. PMT proposes that people protect themselves based on threat and coping Appraisal. It explains how people react to threats and take protective measures to reduce their risk of harm. Laato et al. (2020) adopted the protection motivation theory with 294 Facebook users from Bangladesh to appreciate the relationship between online information trust, information overload, sharing of unverified COVID-19 information, and COVID-19-related cyberchondria. Kim and Tandoc Jr (2022) surveyed 1,023 Singapore residents to investigate the consequences of receiving online COVID-19 prevention misinformation based on the protection motivation theory. Naeem and Ozuem (2022) combined the protection motivation theory and the theory of rumor transmission to recognize how socially shared misinformation, and rumors may increase motivation to protect personal interests and the desire to panic buy across the world. Overall, the protection motivation theory is a valuable framework for understanding how individuals respond to threats and can be applied to a wide range of contexts, including issues of health and political misinformation.

**Social network theory** posits that social groups could exist as personal and direct social ties that link people who share common beliefs and values or formal, impersonal, and instrumental social links (Durkheim & Tönnies, 1893). Moreno (1934) modified this theory by developing sociograms, a graphical illustration of social links to investigate interpersonal relationships. This theory application in our review includes helping to determine relationships between people, groups, organizations, and society. Guided by this theory, White (2014) used it in their approach to illustrate how inaccurate research, media, and public opinion through community ties and social networks led to a reduction in the use of vaccinations in the U.S. and an increase in disease outbreaks (for example, measles). This theory, therefore, can be used to understand how media or a particular group can reshape health knowledge through misinformation and change public health behavior. Mututwa and Matsilele (2020) embraced the theory to develop a qualitative study to explore how some international celebrities announced their COVID-19 infection using their Twitter pages. In addition, Roberts et al. (2017), through the lens of this theory, investigated 109,400 to understand the disparity of Ebola infection news. Therefore, social network theory helps us understand the essence of interrelationships, implications, and impacts on society.

**Fallacy theory** derives from logic theory and relates to arguments that seem correct but are not (Musi & Reed, 2022), thereby misleading. Musi et al. (2023) adopted the Fallacy theory to counter the fake news phenomenon using immunity chatbots. Likewise, Musi & Reed (2022), through the lens of this theory, address misinformation issues by providing a systematic approach for classifying and analyzing different types. Furthermore, Musi et al. (2022) used it along with the logic theory to explore the best way to counter the challenges associated with infodemic and propose reverse engineering, which is the manipulation of information. Musi and colleagues then suggest the means of becoming fact-checkers through critical thinking and digital literacy. This suggestion is timely because, if embraced by many, it will go a long way to mitigate against misinformation.

**Signal detection theory** provides value for humans to differentiate between fake and real news. In our study, Batailler et al. (2022) used it to separate two distinct aspects in identifying fake news: separating fake from accurate information and response biases to consider news as fake or real irrespective of news veracity. Batailler and colleagues adopted it in analyzing existing data sets to unravel two different aspects of the label of fake news to provide more insights into how cognitive reflection, partisan bias, and previous exposure affect the identification of fake news. Guided by this theory, Wagner and Skowronska (2019) designed an experiment where they exposed participants to a list of words to examine whether prior exposure to false information impaired recognition memory. And Wasike (2022) adopted it to examine how social media influencers impact people’s engagement with COVID-19 misinformation. Signal detection theory is a useful tool for identifying misinformation and biased responses. It can be applied in real-world situations to improve understanding of how people identify and react to misinformation.

**The theory of motivated reasoning** suggests that people think in alignment with their uniqueness and established point of view (Gaozhao, 2021). It helps determine how the social context shapes people's feelings, thoughts, and behaviors. Li et al. (2022) adopted this theory to evaluate information and test for biases in news reporting. In addition, Walter et al. (2020) used the theory as a lens to investigate the effectiveness of fact-checking in fixing
political misinformation while analyzing data from 20,963 respondents. Finally, this theory guided Ross et al. (2021) in two studies using diverse pools of participants (n=1,973) to examine the motivation behind sharing misleading partisan information.

**DISCUSSION**

This review study examines the theories guiding misinformation research in social science and humanity areas. Our analysis provided answers to our research questions. For the first research question: What theories have been applied to guide misinformation studies? Our review found 124 specific theories that have been applied to misinformation research in social science and humanity areas. The most frequently used theories include Conspiracy theory, Inoculation theory, Fuzzy-trace theory, the theory of planned behavior, and Framing theory. Researchers have widely used conspiracy theories to study misinformation.

For the second research question: What are the disciplines or fields these theories belong to? We identified more than 24 fields that these theories belong to. Most theories belong to political science, psychology, communication, sociology, and economics. We found it challenging to identify the discipline or field for some theories in Appendix 1 on our Google sheet. They may belong to multiple areas. For example, Discourse theory provides a framework for analyzing language, communication, and power. It suggests that language is not simply a tool for expressing ideas but is instead a complex system that shapes how we understand and interact with the world. It could be categorized as a theory in linguistics or communication. Some theories were labelled as interdisciplinary in Appendix 1 as we think they could be classified into more than one fields.

For the third research question: How have these theories been applied in misinformation research? We took a closer examination of the 11 most frequently applied theories to find out how they were used in our dataset. The application of these theories can be summarized into the following functions: (1) To design a study. For example, theories could be used to design questionnaires or experiments (Irenoа, 2021; Ross et al., 2021; Wagner & Skowronski, 2019); (2) to explore or investigate a phenomenon (Bolsen, Palm and Kingsland, 2020; Lewandowsky, 2021; Lewandowsky et al., 2013). (3) To test the impact or effectiveness of a treatment (Li et al., 2022; Nyhan et al., 2016; Walter et al., 2020). (4) To explain study results (Hrcaková et al., 2019; Irenoа, 2021; Musi & Reed, 2022); and (5) to be part of a new theory (Musi et al., 2022).

Our study may benefit researchers and educators in Library and Information Studies in multiple ways. This paper is the first to examine theories that have been applied to misinformation research. The theories we identified from the review may inform other researchers when they look for theories for their studies; our study deepened our understanding of the popularity of misinformation research – many disciplines and researchers are conducting studies in misinformation; for LIS education, this study informs instructors’ theories, definitions, and application that should be included in related curriculum on information behavior, information evaluation, and information literacy; lastly, the systematic review approach used in this study could be applied by other researchers to explore other topics. Especially our experience in the research may be helpful to others. We found that it was not always easy to identify the theories applied by a study. This type of literature review requires that the coders read the entire paper; to determine the dataset, we went through multiple steps, and we had to read more than 600 papers initially. Only a small part of them used theories. Besides, some papers are not empirical studies, so we dropped them from our dataset. Also, apart from the articles, we used other tools to assist in understanding the theories and their fields, such as Google, ChatGPT, and Wikipedia.

Our study has some limitations. First, some related literature may have been excluded since we narrowed it down to only articles meeting our criteria and used only three databases Scopus, ScienceDirect, and Web of Science. Some related articles may not be included due to the query terms we used, or may have been in other databases or published in other venues. We also dropped some articles that were not written in English and those that did not adopt or specify any theories after reading the entire paper. Moreover, some of the latest applications of the theories of misinformation may have been overlooked as some related articles may have yet to be published.

**SUMMARY AND CONCLUSION**

This paper reviewed the existing literature to identify theories that have guided misinformation studies in social science and humanities and to understand how they have been applied in those studies. Through a systematic approach, we selected 273 articles published from 2012 to 2023 and analyzed them to determine the theories and how they were applied. Our review identified 124 social science and humanity theories applied in the 273 studies. These theories belong to more than 24 fields. We took a closer examination of the 11 theories that are most used in misinformation studies. We found that theories have guided misinformation studies in various ways, including questionnaire design, interpreting misinformation phenomena, and spread behavior, detecting aberrations, and explaining research results.
In sum, librarians, researchers, and theory users could emphasize preventing private ignorance and publicizing knowledge to combat the spread of misinformation. It underscores the role of library and information policies in promoting informed decision-making and fostering a more knowledgeable society.

Our future study will explore the non-social science theories, models, and frameworks for fighting misinformation. Then, we will work to create a misinformation ontology that helps design applications to detect and correct misinformation and create educational materials on evaluating information and information literacy.

ABSTRACT
This paper details the findings from a study investigating the efficacy of community-based and -organized information sessions for dispelling public health misinformation around COVID-19. The authors used community-engaged participatory action research methods to co-organize town halls with community members, groups, and officials to disseminate COVID information for two New Jersey towns and townships with differing demographic compositions in late 2020 through 2021. These sessions aimed to share reliable, trustworthy public health and safety information around the COVID-19 pandemic. This small-scale, qualitative study suggests that this type of hyper-localized information session where residents can interact with local leaders and talk openly about local problems around public health can be a point of connection for people with their community, that helps them access and address localized public health problems in myriad ways. In so doing, this study suggests ways to re-imagine public health information and communication practices to promote informational justice.

KEYWORDS
Community-engaged research; participatory action research; Covid-19; misinformation; community information sessions; public health information, hyper-localized information sources; online forums

INTRODUCTION
Research suggests that in the context of attenuated public institutions and rampant misinformation, localized engagements with experts may work to diffuse the harmful effects of misinformation (Burgess et al., 2021; Kuppali, 2020). In this study, the term misinformation is used as a catchall to describe false and misleading information spread with and without the intention to deceive (Jack, 2017), because this study focuses on outcomes rather than intentions. To date, there is research in library and information science around hyperlocal community information sessions as a site to increase local engagement with public health issues and combat health misinformation (Paris, Carmien, et al., 2022), but it far from normalized in the field. This study builds on Paris’ previous work as a step towards normalizing these interventions in the field. While there are investigations of community sites of public health campaigns (Allen et al., 2020; Bossaller et al., 2022; Luo, 2018), and many studies around developing technical information systems to support public health (Clarke & Steele, 2015; Unertl et al., 2016; McCall et al., 2022) library and information science researchers can also more fully engage participatory action research or community-engaged methods to enact or simulate a public-forum experience to generate dialogue and recommendations about misinformation, public health issues, and community safety as an end in itself. This study aims to provide an example of such an endeavor that addresses Covid-19 misinformation in New Jersey, one of the hardest-hit states at the onset of the pandemic, that has seen its share of localized misinformation around Covid-19 shaping daily life (Allred et al., 2021; Associated Press, 2021).

The authors work was motivated by informational and medical justice initiatives designed and implemented by minoritized communities for to respond to medical discrimination and misinformation around public health issues by cultivating their own medical and informational practices (Burgess et al., 2021; Nelson, 2011). Following these informational and medical justice interventions’ methods, the study at hand used rigorous participatory action research methods combined with intersectional analysis (Haines, 2022; Harrington et al., 2019; Author et al., 2021) to help plan and execute live online forums in two towns in New Jersey where they live and have community ties, each with differing demographic makeup: Franklin Township, NJ and the community cluster of Maplewood and South Orange, NJ. While both communities lean towards Democratic party affiliation and are white-majority communities, with 25% of the Black population comprising around 25% of the total population, Franklin is in Central Jersey and is more diverse, with a lower proportion of white inhabitants and a higher proportion of Asian and Pacific Islander and Latinx residents (U.S. Census Bureau, 2020a, 2020b, 2020c). The South Orange and Maplewood cluster lies in closer proximity to New York City and Newark with a median income of around $151,000 (U.S. Census Bureau, 2020a, 2020c). Franklin township has a lower median income ($94,000) (U.S. Census Bureau, 2020b).

These online information sessions were initiated by researched and co-hosted by local community groups, elected officials, and libraries from November 2020 to May 2021 to understand how this subsample of the New Jersey population trusts and responds to localized public health issues around the pandemic and how effective these hyper-
localized information sessions might be in addressing public health misinformation. This study helps those interested in combating misinformation better understand localized perspectives on public health practices related to the pandemic and promote community dialogue to re-imagine information systems to promote informational justice.

LITERATURE REVIEW
To effectively ground our study of hyper-localized engagements and public health misinformation, we looked to the contemporary example of COVID-19, rife with misinformation leading to disastrous public health consequences. Here we first outline the scientific health communication and misinformation problems related to Covid-19 to open a conversation about scientific health misinformation in general and the difficulty of dispelling this misinformation. Next, we look to successful examples of addressing and dispelling science and health misinformation, identifying how public health misinformation can be understood as a localized phenomenon and can be addressed through community-based information sessions.

COVID-19 information ecology
Politically-charged misinformation has been a growing problem for public health officials, even before the pandemic (Fallis, 2009; Hussain et al., 2018). The context and motivations of such misinformation can vary. People often look online first for health information because the barriers to seeing a health professional are so high, or because they are directed to by mobile health applications (Costello & Veinot, 2020; Pluye et al., 2019). In some circumstances, incomplete knowledge, mistrust in the medical industry, and unverified rumor drives misinformation around public health issues (Donovan et al., 2021). In any case, health misinformation can be incredibly damaging to public health outcomes because people have difficulties grappling with what is true and false, and how to act accordingly (Chi et al., 2020). Once this false and misleading information reaches people, it can be difficult to dispel the false beliefs and claims (Ognyanova, 2020; Southwell & Thorson, 2015; Tromble & McGregor, 2019).

In 2020 the Covid-19 pandemic was characterized as an “infodemic” by the World Health Organization, and aspects of the phenomenon have been studied by many researchers who suggested solutions in light of a large-scale misinformation event (M. Chong et al., 2022; Donovan et al., 2021; Starbird et al., 2019). Online spaces have been vectors of misinformation as platforms reward false information as it receives higher engagement and travels faster and spreads wider than true information (Singh et al., 2021). Moreover, misleading and false content left unchecked on sites like Facebook, YouTube, and WhatsApp often directs users to insular sites and chat groups that peddle even more nefarious disinformation (Paris & Pasquetto, 2024). Researchers found this to be especially true with Covid-19 misinformation (Bridgman et al., 2020). This information glut became dangerous at the pandemic’s onset as people had few resources to process and filter the information, namely inadequate information about the novel coronavirus, combined with a widespread mistrust in public health institutions, scientific expertise, and government entities (Donovan et al., 2021; Verma et al., 2022).

Covid-19 misinformation is particularly harmful as the virus is a public health issue and requires collective adherence to public health rules to limit spread. Those acting on misinformation engage in behavior that puts others at risk, such as refusal to wear masks, be vaccinated, and or abstain from gathering in large groups in close proximity (Y. Y. Chong et al., 2020). Further, those exposed to COVID-19 misinformation act on it in ways that are detrimental to themselves—after the circulation of the false claim that hydroxychloroquine cured COVID-19, the rush to consume these products caused a rash of poisonings and a shortage that, in the case of hydroxychloroquine, threatened the health of people with lupus and others who depend on those drugs (Aquino & Cabrera, 2020).

The early pandemic failure on the federal level to put out a cohesive response or plan created an information vacuum which U.S. states scrambled—or failed—to fill. The varying guidelines between states left people further confused about best practices to mitigating the spread of COVID-19, which in turn, opened the door for mis- and disinformation. In many cases, the federal government itself, particularly former President Trump, and administration officials, served as a prominent source of misinformation (Wang et al., 2022). This phenomenon further erodes support for public health and trust in institutions. It is not just ever-changing information about the virus, and the lack of credible voices; often, people who believe false claims spread by disinformation are aware of the information and activity accepted and promoted by the government, medical and scientific establishment, they do not trust these institutions (Kuppali, 2020).

The multifaceted problem of trust
Consistent messaging about mask-wearing did not convince people who believe Covid-19 is a hoax or people who think it is their right to not wear a mask (Verma et al., 2022). People's attitudes about information, in particular their trust in this information, is as important as what information they are exposed to (Sinatra et al., 2014). People are more likely to seek out and believe information that is in accord with beliefs they already hold, while downplaying or ignoring information that challenges those beliefs (Southwell & Thorson, 2015). At the same time, people are more likely to believe new information from a trusted source, or one that most of their social group believes. Meanwhile, the world has transitioned into a high-choice information and communication environment where
people can gather information from thousands of different channels, and never see something they do not agree with (Southwell & Thorson, 2015). Non-mainstream news media, such as podcasts and influencer channels on social media are designed to cater to consumers by making emotional appeals for inclusion into a persecuted in-group, which is particularly effective in garnering trust (Lewis, 2018).

The exaggeration of persecution and belonging, and doubt for political purposes can take many forms (such as using the gap between scientific and colloquial terminology to claim that because something is a “theory” that means there is room for debate or it is unproven) (Sinatra et al., 2014). As issues around COVID-19 are politicized, people become less open to acting in accordance with the public good. Lowered trust in science means that people may be less likely to follow CDC guidelines such as masking and social distancing. Given the existing difficulties in the vaccine rollout, people deciding not to take the vaccine have made conditions ripe for harmful variants that infect, hospitalize, and kill unvaccinated people at high rates (Verma et al., 2022)

Proposed interventions like pre-bunking (Dan et al., 2021), providing corrections (Bode & Vraga, 2021), supplying widespread, high-quality information, and encouraging better informational literacy are partial solutions for the problem of misinformation (Milner & Phillips, 2020; Paris, Marcello, et al., 2022). However, where these informational tactics come from is also a crucial piece of the puzzle. Research has shown that high usage of the internet for socializing correlated with weaker ties with local communities, lower trust of others, and of institutions, and lower contentment overall (Milner & Phillips, 2020). For many of the people who spread the most information, they often know it is not correct; thus, many of the tactics above are not effective (Dan et al., 2021; Ognyanova, 2020; Tromble & McGregor, 2019). Conversely, engagement with local news is closely associated with strong connections to and more activity in the community and voting in local elections (Barthel et al., 2016). People who feel positively about their communities and have close ties with their neighbors also strongly tend to feel positively about local news, and therefore have high trust in local news sources. These findings from Barthel and co-authors (2016) motivated our study to focus on community engagement as an effective means of combatting public health misinformation.

Community engagement around public health information

Thus, researchers have suggested that the best solution for misinformation around public health is community-based public health interventions (Burgess et al., 2021; Kuppali, 2020). Burgess and their co-authors (2021) noted in their published study of public information sessions around Covid-19 in 2020, that public health responses must be adapted to each local context, using a deep understanding of what each specific community needs. This requires that public health officials collaborate with and empower trusted local leaders, giving them the resources and knowledge to communicate about and implement public health measures, do outreach and messaging, and dispel false information. Local public figures are best suited to this task because people already trust them, and they know what their community needs. But this activity also runs the risk of further burdening already over-extended local institutions, experts, and individuals (Pierre et al., 2021), and in many cases, only reaching those who are already interested in the narratives and information presented at these events, while those who need to hear the messages the most do not attend and remain mistrustful (Paris et al., 2022). This phenomena is not new, one example of meeting these issues head-on happened in the 1960s with the Black Panthers Party (BPP) Free Health Clinics that trained local, Black medical experts to provide care and information around health issues that affected Black communities, e.g. sickle cell anemia, prenatal care, diabetes treatment, as hegemonic, White-run medical institutions discriminated against Black communities, as the medical industry predominately used Black test subjects, extended harms, and segregated Black patients out of quality medical care (Nelson, 2011). The BPP medical interventions were an intervention in creating infrastructures, meaning people and their social practices around various systems of communicative, technological and scientific tools (Star & Ruhleder, 1996), for informational and medical justice.

Echoing this history and drive for informational justice, Burgess and her co-authors (2021) conclude in their study running town halls around Covid-19 in Black communities that it is important not to conflate all vaccine hesitancy with conspiracy theories; marginalized people have plenty of good reasons to be distrustful of their governments. So the medical establishment must meet concerns about the vaccine with understanding and real explanation. Public health officials should, through existing community channels, such as faith groups, sports and youth clubs, local online networks, schools, and the like, and ask local leaders in those areas to take charge of vaccine messaging and rollout and community engagement (Burgess et al., 2021). Forums for local community leaders and members builds communal trust, makes sure each community's unique and specific concerns and challenges are addressed, and increases receptivity to public health messaging, and overall, promotes better public health outcomes.

RESEARCH QUESTION AND METHODS

Given that misinformation around Covid-19 is rampant as it is politicized and rewarded by platforms, we wanted to provide a participatory context that might be useful for people grappling with the information glut in their own lives, faced with risky public health behavior of those around them, and struggling with the safest course of action for
themselves and their loved ones. We wanted to provide this context, understand the particular issues of trust in information respondents grappled with as they attended these events, and gauge the efficacy of such participatory approaches for addressing Covid-19 misinformation to provide trustworthy public health information. Our study is guided by the research questions and sub-question below:

RQ1: What informational problems did respondents express drove them to the events?
RQ2: What were respondents’ level of trust in COVID-19 information from various sources?
RQ3: How, and in what ways, were these informational events effective and not effective for respondents?

Methods & site description
One way that the participatory information sharing contexts described in the literature can be realized is in town halls, or localized information sessions where local people can ask questions directly to experts (Bejarano & Yanovitzky, 2018; Burgess et al., 2021). In the state of New Jersey, where our intervention was staged, Bejarano and Yanovitzky (2018) studied how state-wide town halls influenced community perceptions of opioid abuse and collective efficacy to fight opioid abuse and addiction. The state of New Jersey ran town halls in each of New Jersey’s 21 counties and the researchers ran surveys, polling nearly 2500 attendees on their perceptions and attitudes on opioid use. We used Bejarano and Yanovitzky’s work as we built our own, as their large survey gauged the outcomes and utility of town halls over the public health issue of the opioid epidemic across New Jersey.

This project departs from Bejarano and Yanovitzky’s in that it employs methods variously referred to as participatory action research (Burgess et al., 2021; M. Currie et al., 2016) and community-based research (Harrington et al., 2019; Unertl et al., 2016) to engage a concerned public, of which the authors are an active part, on a relevant topic and provide an opportunity to express themselves in a participatory space. The authors organized virtual information sessions in conjunction with community partners: the local government in Maplewood, and with a local grassroots organization Community Coalition on Race (CCR) in South Orange, and in Franklin Township, these events were held in conjunction with local government and the public library.

These towns were chosen because of the authors’ situatedness in these towns and because of their diversity and demographic differences mentioned in the introduction. Franklin township was more recently rural than Maplewood and South Orange in Essex County, and these communities have been longer known as hubs in Northern New Jersey as the population and industrialization moved outward from New York City and Newark (Birkner et al., 2012). Franklin Township and the Maplewood/South Orange cluster’s disparate historical and current demographic compositions make them rich sites for comparison.

Positionality and access
In any interpretative study, researcher positionality is a methodological concern (Paris & Pasquetto, 2024) as it shapes data collection and analysis. Authors Paris and Costley White have a background in participatory action research (Currie & Paris, 2018) community-engaged methods (Currie et al., 2016), and activist research (White, 2016) which motivated their focus on these research questions within the hyper-localized contexts of New Jersey where they live and participate in movement building and organizing. Researchers used their contacts to organize the events. In the case of Maplewood, the town hall was already planned, and Costley White who is a resident and knows local official who had planned the event, asked for the ability to survey the audience; similarly with the South Orange CCR event, she regularly engages with this grassroots group asked for the ability to send surveys to participants. In Franklin Township, Paris set up an event with the local library and invited the mayor and suggested others to invite to be on the panel. Franklin Township public library both publicized and hosted both events through its Zoom portal. Research respondents were consented into the study using the authors’ university IRB protocols.

Interventions and data collection
These informational sessions included a panel consisting of a mix of expert epidemiologists, local officials, public health experts, and librarians. As these individuals are local public figures, they are named in the paper. Due to the pandemic, these sessions were hosted online and made available to the public through the collection of email addresses that community partners maintained. These sessions were recorded. Patrons submitted questions beforehand for the panelists to answer, moderated by Paris and Costley White in respective townships. Following the event, attendees completed a voluntary, anonymous survey that allowed them to answer questions about their information habits, how trustworthy they thought the event was, and what types of things the panel clarified for them. Further, these surveys allowed us to connect with people who might be interested in talking more in-depth about the issues of health misinformation that affect them. These interviews were conducted via phone because of the pandemic, recorded via audio, and later transcribed.

The following events were staged from November 2020 to May 2021. Here we outline the events structure and the demographic responses from survey respondents, as well as how many interviews from each event we performed.
November 2020: Town Hall Maplewood, NJ and South Orange, NJ
Fifty-six survey respondents either attended a town hall event on Sunday November 22, 2020 from 7:30 - 9pm over Zoom, or viewed the event via YouTube recording. Respondents were predominantly white women, though 11 men responded and 13 of the 56 respondents identified as Black and African American (11), Asian, and Southeast Asian (2). No respondents from this event agreed to be interviewed. Respondents ranged in age from 21 to 84, concentrated more heavily in age ranges 40-50 and 70-80. There was a fairly even split in survey respondents living in Maplewood (30) and in South Orange (24).

February 2021: Franklin Township Library-Hosted Q&A Session
Thirty-four people attended the first Franklin Township Library-Hosted Q&A session held via Zoom. This event hosted Dr. Mayor Kramer, Dr. Namitha Reddy the Somerset County Director of Public Health, and Director Commissioner of Somerset County, Shanel Robinson. Director Commissioner Robinson spoke directly to the efforts that Somerset County and Franklin Township were undertaking to ensure that Black, Latino, and elderly communities had access to vaccines, as well as to address questions around racial health disparities in Somerset County during the pandemic. Most of the 12 attendees who responded to the survey were over 60, three-quarters of attendees responding identified as women, and one-quarter reported their race as South Asian, Latinx, and Black or African American, while the remaining three-quarters identified as white. Three agreed to be interviewed. All respondents were from Franklin Township or Somerset County.

February 2021: Community Coalition on Race Maplewood and South Orange, NJ
Dozens of people gathered virtually for the Community Coalition on Race (CCR) Session held on February 28, 2021. Dr. Camara Phyllis Jones was the only one of the four panelists to discuss in-depth the structural arrangements primarily racism and capitalism, leading the outsize impact of the pandemic on Black communities. Only five respondents, all of which were Black women responded to the survey; three agreed to be interviewed.

May 2021: Franklin Township Library-Hosted Q&A Session
The final information session was held May 5, 2021 via Zoom in conjunctions with Franklin Township Public Library. Mayor Kramer was again an invited guest, and while Dr. Reddy could not attend at last minute, Kramer invited Dr. Ron Nahass a local epidemiologist. Of all the events, this was the most sparsely attended and survey responses were the lowest. Survey respondents all identified as Black or African American women from the Franklin Township community; one person agreed to be interviewed.

Survey and interview questions
The survey and interview questions were adapted from Bejarano and Yanovitsky’s (2018) intervention collecting surveys on town halls in NJ around the opioid epidemic. Our survey questions are included in the appendix (Survey Question Appendix: https://rutgers.box.com/s/whxotdu68arevmjfgfx22vybn5ng77bh) focused on COVID-19 and related informational public health issues, as well as a few questions about where respondents get information, and what sources they trust.

As adapted from Bejarano and Yanovitsky’s (2018) study around communicating public health issues, interview questions were semi-structured to elicit a relaxed and engaging conversation about the events, and to gather more qualitative nuance on the survey responses (Alvesson, 2003). Each of the questions below was followed with a “why” or “why not”, as relevant, if it was not expounded upon in the response.

- Tell me a bit about yourself, where you live and how you identify.
- Why did you attend this event?
- What about it was compelling to you?
- Where do you get most of your health information?
- Where do you get most of your news?
- What did you learn about COVID-19 at this event?
- Do you feel that people in your community struggle with misinformation?
- Do you feel that people in your community struggle with misinformation around COVID-19?
- Do you feel that local officials, medical experts, and leaders are responding appropriately to COVID-19?

**Figure 1. Interview questions**

Analysis
The analysis of the survey data for each intervention was performed in Google Sheets populated from the Google Forms where participants took the surveys. The authors collaboratively and iteratively analyzed the survey findings,
the interviews, and video transcripts using their knowledge of political communication, participatory action research, intersectional analyses of misinformation, and information retrieval and interpretation. We developed codes based on aspects to the research questions, which included: trust, efficacy, misinformation, race and gender that are provided in the findings. Then, as we continued to analyze the data, themes in the discussion section subheadings emerged in relation to the research questions.

**Strengths and limitations**
This type of event and the assessment of these types of events will continue to be useful as the pandemic and its fallout unfurls—evidence while it has been declared over (Jørgensen et al., 2022), it will still be a long road ahead. The authors conducted this study as the pandemic’s context was rapidly changing. On one hand, this provides us with robust data on how informational needs changed as vaccines became available and as new variants emerged. Finally, though the study is small and highly locally contingent, the findings and analysis provide a qualitative snapshot of useful observations that can be used in the small-scale, localized settings described to develop practices that promote informational justice around misinformation topics, as well as support the possible utility of organizing hyper-localized engagements around misinformation and the study of those events in the form of participatory action research. As the N is small, we report themes broadly below.

**FINDINGS**
We found four main themes of interest emerged in the data: the first is the type of misinformation the respondents claimed to see or reported needing help with, which tied closely with the nuanced answers respondents gave regarding their motivation for attending the event. These coincide with the theme of trust, or what media and outlets the respondents distrusted and trusted and why, as well as why they did not see these types of events as trustworthy. Finally, issues and components of efficacy of the events are described in the last subsection.

**Topics and motivation to attend: across sites, over time**
As the events were held over seven months, in different localized New Jersey locations, with diverse demographics, the types of community questions around misinformation asked at the sessions varied greatly. In November 2020 Maplewood residents were concerned with the science behind COVID-19, the progress on a vaccination, and how the community was responding to the virus, specifically regarding public school protocols. In February of 2021, vaccines began to roll out in New Jersey; thus, the Franklin Township public library’s event focused on vaccine science, epidemiology, and protocols, where to get it, how to make an appointment, which vaccines were best, and what to do if someone couldn’t make it for their second dose. Later that month, the event held by the Community Coalition on Race (CCR) in South Orange and Maplewood, NJ, focused on the pandemic precursors and official response, as well as how inequitable practices in health institutions and governments contributed to vaccine hesitancy in the Black community, and discussed how to overcome vaccine hesitancy. Finally, the last event held in May 2021 with the Franklin Township public library occurred just after a vaccination wave in which adults who wanted to be vaccinated, were vaccinated, or were in the process of being fully vaccinated. Many questions surrounded reopening protocols and what to do about children, immunocompromised people, and vaccine refusal in their social circles and local communities. At the same time, the delta variant has just exploded in India, and people were concerned about different strains of COVID-19, whether there would be the need for new vaccines or booster shots, and how must they needed to worry about new strains if they were already fully vaccinated.

Respondents for three of the four events overwhelmingly claimed they attended the event because they wanted to learn more about Covid-19 in their community. Respondents for the CCR event identified that they were most interested in connecting with other community members around COVID-19 and seeing what they could do to help. They were also interested in learning what was being done about COVID-19 in their community, learning about the science behind vaccines, and how to get one.

**Trust**
Interview respondents also noted that they encountered so much information around COVID-19, it was hard to know what information would help them make choices for themselves and their loved ones on a day-to-day basis. The survey results showed that the town hall was unanimously rated “completely trustworthy” or “mostly trustworthy” across events. While most respondents found local news and radio and friends and family to be more trustworthy than other media such as state and national news sources, a few suggested greater trustworthiness in national news sources like the New York Times and National Public Radio programming as well as governmental agencies like the Centers for Disease Control and Prevention. However, all the respondents and interviewees found these media or sources as less trustworthy than the local information session in question. This, along with the other findings, suggests that this type of town hall event, where residents can interact with local officials and talk about local problems around COVID-19 can be very useful for residents, as it at once connects them with trusted community members and officials, helps them access and address localized problems in myriad ways, and honors them as stakeholders in community issues. However, while the majority of those attending the first Maplewood, NJ event
found it to be highly trustworthy, survey respondents who did not view it as trustworthy expressed disagreement with Dr. Griffin’s (who does not live in the community) characterization of the activities of school-aged kids in their community.

**Intersectionality and trust**

Overall, the CCR event in South Orange, NJ was one of the most trustworthy, according to participants who spoke with us. Though few of the attendees responded to the survey, those who agreed to talk with us afterward had excellent insights as to why they thought this engagement was so useful and trustworthy. All respondents were Black women who make decisions for their household and extended family and were appreciative of Dr. Jones’s expertise as a physician and epidemiologist in racism as a public health issue and that as a Black woman, she knew the unique problems they faced. They also said that they appreciated that instead of focusing on literacy or individualized solutions, Dr. Jones spoke about systems like social hierarchies, racism and capitalism, as contributing to the problems with the pandemic and the destruction in its wake, as well as the botched responses to the pandemic and the deserved mistrust that emerged. One interviewee who attended the event explained:

“I love the fact that [Dr. Jones] brought it full circle. And you know we are speaking about the virus the vaccine our community as one whole system and not just a society we tend to put things in boxes. How have to look at everything just full circle and how will a quarantine be effective when people don't have adequate housing, what happens when you put people who have to work on the front lines everyday who live in close quarters with the elderly? You have to think of all those things to be able to just connect all of those dots. And she did in a way that I just loved. So, I thought that was probably the most powerful thing. And this echoes the other presentations that I saw which is they were speaking to the data. This vaccine is going to keep you off of a ventilator. And you know, we know that most people who go on a ventilator do not do well and typically die. So you know, took like a basic equation, you know, vaccine equals no ventilator, equals no death” (Respondent, interview, March 18, 2021)

Across the CCR and the first Franklin township event, there were instances of Black women who identified as members of Black racial groups and had been mistrustful of traditional medical expertise whose opinions on and openness to being vaccinated changed as a result of the town hall and ones like it. Interestingly attendees at the last event in May 2021 in Franklin Township that responded found this mostly trustworthy at best, in contrast to the previous events that were rated completely trustworthy, and mostly trustworthy. But they still found it more trustworthy than other media. The possible reasons underpinning this finding will be further unpacked in the discussion.

**Efficacy**

Across events, respondents claimed they learned new information about how prevalent COVID-19 is in the community, what causes spread, what local officials were doing to address the virus at a community level, and how to help in the fight against spread. As the vaccine became available, respondents articulated feeling more at ease about vaccination. At the first event in Maplewood, NJ, while folks claimed they left feeling more empowered, overall, they said they were less confident that the community can effectively respond to COVID-19. This was similar to the findings from the CCR event. Respondents attending the Franklin Township public library events conversely reported feeling more confident that their community can respond to COVID-19. Overall, the CCR event respondents reported the highest level of new knowledge and confidence on what to do about COVID-19 because of the event.

**DISCUSSION & ANALYSIS**

**Understanding trust and relationships to misinformation**

Most interview respondents expressed frustration at the proliferation of information about COVID-19, some of it true, some of it false, was a hardship for them. This phenomenon aligns with Southwell and Thorson’s (2015) and Verma et al’s (2022) observation that high-choice information and communication environment where information can be gathered from thousands of different channels. While we did not encounter anyone who doggedly adhered to misinformation, it was a topic on attendee’s minds, as shown through their decisions to attend, and through the instances of misinformation that all interview respondents claimed to have encountered either firsthand or had experienced colleagues, friends and loved ones sharing. Interview respondents, as well as the survey responses from the attendees of the events showed that the topics of COVID-19 and how communities responded were important to attendees. The responses suggested a willingness to believe the virus was real, and something can and should be done to mitigate its spread, as well as trust in the expertise of local officials, medical practitioners, and science, more generally. This finding supports Sinatra’s (2015) suggestion that people’s attitudes about information: how they trust it is as important as the information they are exposed to. In this case, people attending had the same mindset as those producing and speaking at the events, which made information uptake easier and more helpful. But, as we did not encounter any attendees disagreeing with the information presented, or even finding the event “not trustworthy”, it
politicization of health information, which is premised on the with opposing viewpoints around expertise and information. This observed phenomenon also underscores the further negotiation between particular group rather than based on the veracity of any piece of information (Sinatra, 2015).

However, there were instances of negotiation between one’s group affinity and accepting the expertise of public health and medical experts, as the Black women who expressed initial reticence to accepting official statements and traditional medical expertise where experimentation was concerned, especially in relation to the vaccine, became more open to being vaccinated because of the town halls she had attended. This supports Burgess et al (2020) conclusion that it is important to understand vaccine hesitancy in minoritized communities as a unique phenomenon to be met with deep explanation around structural issues, as they have valid reasons to be distrustful of governments and the medical establishment.

Informational justice: localized, bottom-up expertise and possibilities for increased efficacy

On this note of group affinity, and racial group belonging, in particular, we must mention that the meetings led by Black women were rated as more trustworthy and illuminating by other Black women, as was the case with the CCR event. The first Maplewood event was run by one of the authors, a Black woman, and the panelists included people of color. The first Franklin Township event included women of color panelists, and was also rated as highly efficacious. The last event at Franklin Township public library where the panel was solely comprised of white men was significantly lesser attended, and seen as less trustworthy than the others. At the same time, respondents for that event were Black women. This observation also supports Burgess’ (2021) suggestion that asking local, trusted Black leaders to take charge of public health messaging and rollout would be more efficacious in building trust, ensuring the community’s specific concerns and challenges are addressed, and increasing uptake of information and related decisions. This observed phenomenon presents an actionable practice to promote community dialogue that engenders informational justice of the type offered by the Black Panthers’ Free Medical Clinics (Nelson, 2011) that focuses on the informational needs of marginalized communities around health issues being more efficiently met by local members of those communities organizing to build out systems of practice and communication around medicine and public health, that include community engagement around scientific expertise, and technologies.

These events and the responses around them indicate that basing these live informational events within communities, hosted by community organizations can be incredibly trustworthy, effective, and build opportunities for growing community bonds. Though the first Maplewood event and those Franklin Township events were rated highly, they might have been rated higher if they had included more local experts, such as scholars or local physicians, that weren’t strictly government representatives, as the government is not always seen as a reputable source of information. That the CCR event featuring local public health expert and woman of color and that the other three events were organized and moderated by local scholar activists suggests that localized expertise, such as those held by local scholar-activists can be a useful and compelling community resource that can be leveraged against public health misinformation, and perhaps around misinformation more broadly.

The declining participation over time suggests that perhaps the virtual aspects of these events is an obstacle to efficacy. It suggests a sense of Zoom fatigue that may have been a result of the onflow of programming provided on Zoom through the course of the pandemic, and as weather in New Jersey became warmer and as people became vaccinated, people were spending less time in front of Zoom. The virtual aspect of information dissemination and data collection during the pandemic has been an obstacle to institutions and professions everywhere. However, this study suggests that these types of virtual events can be incredibly efficacious and helpful in unique public health crises similar to those in the U.S. pre-vaccine, for people who have internet access, free time, and the desire to learn more about a given public health issue from experts, widely construed.

CONCLUSION

This study provides a qualitative snapshot of small-scale hyper-localized town hall information sessions in diverse and distinct locations New Jersey. The authors are visible members of and have strong contacts in the diverse communities where these events were held. The authors co-organized four town hall events with local institutions in North and Central New Jersey in 2020-21 and collected data on these endeavors. Overall, respondents found the town hall more unanimously trustworthy than any other sources of information--local, state, and national, newspapers and news sites, radio, television, social media, and word of mouth. This, along with the other findings suggests that this type of town hall event, where residents can interact with local officials and talk about local problems around public health, specifically COVID-19, in this case, can be very useful for residents, as it connects them with trusted community members and officials, helps them access and address localized problems in myriad ways, and honors them as stakeholders in community issues.
This study supports others (Barthel et al., 2016; Burgess et al., 2021) that suggest that as misinformation is increasingly highly targeted, so too must be tactics to address misinformation, particularly in events that affect the broader public like the COVID-19 pandemic. Hyper-localized informational events like these are highly targeted and contextualized. Studies of hyper-localized public health communication and information sessions across the country or sections of the globe around similar public health or public facing issues prone to misinformation would also be a welcome next step for future research.

As the COVID-19 pandemic wears on with variants, boosters, and continued misinformation around public health issues, and as climate change, economic inequality, and systemic racism continue pose problems of global concern, we suggest informational, community-building interventions such as these that are staged by community members, for community members, may be a potent antidote against the influx of information problems likely plaguing us in the near future.

From Principles to Practice: Comparative Analysis of European and United States Ethical AI Frameworks for Assessment and Methodological Application

Pierson, Cameron M.  L3S Research Center, Leibniz Universität Hannover, Germany | pierson@l3s.de
Hildt, Elisabeth  L3S Research Center, Leibniz Universität Hannover, Germany | Elisabeth.hildt@l3s.de

ABSTRACT
The Z-Inspection® Process is a form of applied research for the ethical assessment of AI systems. It is quickly establishing itself as a robust method to ethically assess AI in Europe. The process is predicated on the European Union's Ethics Guidelines for Trustworthy AI, outlining ethical principles intended to guide European AI development. In contrast, the United States has only recently released its holistic version of such guidelines, the Blueprint for an AI Bill of Rights. The aim of this paper is to assess the suitability of the Blueprint for an AI Bill of Rights as an ethical framework underpinning the use of the Z-Inspection® Process in the United States. This paper provides preliminary findings of comparative analysis of European and United States ethical frameworks for responsible AI development. Findings outline primary ethical concepts that are shared between respective frameworks. Findings suggest the US Blueprint is suitable as an ethical framework for the Z-Inspection® Process. There are notable omissions within the US framework which would require further development for Z-Inspection® use. Discussion will consider opportunities for adapting Z-Inspection® to the United States context, including contributions from the information professions and research.

KEYWORDS
Artificial intelligence; AI ethics; International information issues; Value-sensitive AI design; Legislation and regulation

INTRODUCTION
Rapid development and deployment of artificial intelligence (AI) is increasingly impacting information ecosystems. Ethical assessment of AI is necessary to ensure the just and equitable distribution of benefits and potential harms, as an information technology impacting almost every aspect of the information society. To insure safety and ethical alignment of AI systems, ethical assessment expressed in regulation and scalable, interdisciplinary mechanisms is therefore required, and acknowledged among major governmental jurisdictions (High-Level Expert Group on AI, 2019; White House Office of Science and Technology Policy, 2022). The proposed European Union AI Act, for example, is informed by the Ethics Guidelines for Trustworthy AI (High-Level Expert Group on AI, 2019). While the European Union (EU) is aiming to establish itself as the leader in ethical AI development, the United States (US) has only recently outlined its own version of ethically informed principles to guide AI development, the Blueprint for an AI Bill of Rights (White House Office of Science and Technology Policy, 2022).

Principle-based guidelines have been criticized as too high level and vague for practical application (Munn, 2022). Application and proposed regulation with high level ethical underpinnings requires processes and ethical scrutiny which are sound and scalable. Similar mechanisms have been proposed, such as embedding ethicists in the design process (van Wynsberghe & Robbins, 2014), ethical foresight analysis (Floridi & Strait, 2020), or algorithmic auditing (Raji et al, 2020). The Z-Inspection® Process, however, is establishing itself as a reliable and robust method to assess ethical issues and tensions of AI systems (Zicari, Ahmed, et al., 2021). This process is developed on the premise of the EU’s Ethics Guidelines for Trustworthy AI and uses the guideline’s ethical principles as a central instrument to guide analysis informing AI development. This process requires applied ethical research within the collaborative participation of researchers and experts across multiple disciplinary and professional fields.

However, there remains no such mechanism in the United States context mirroring the Z-Inspection® Process, predicated on a jurisdictional level expression of ethical expectation. To adopt such a process in the US context, the comparative positioning of the counterpart ethical guidelines must first be understood to assess compatibility and identify opportunities and recommendations for praxis-oriented research and collaboration. The aim of this paper is to understand the extent of similarity in the ethical positioning between jurisdictions, and the plausibility of adopting such a process in the United States. This paper outlines the similarities of the respective frameworks. It will provide an assessment of the US Blueprint for an AI Bill of Rights as an alternative ethical framework within the Z-Inspection® Process. Finally, it discusses considerations for its adaptation to the United States jurisdiction, with implications for information science research and practical and international collaboration.
LITERATURE REVIEW
The European Union’s Ethics Guidelines for Trustworthy AI

The European Ethics Guidelines for Trustworthy AI outlines the ethical principles constituting trustworthy AI in the European jurisdiction (High-Level Expert Group on Artificial Intelligence, 2019). The concept of trustworthiness is fundamentally relevant to the European approach, i.e., the idea that for an AI system to be trustworthy, it must fulfill several preconditions, including ethical alignment in design and development. The guidelines document defines trustworthy AI systems as systems that are lawful, ethical, and robust throughout their entire life cycle. The guidelines characterize four ethical principles (also called ’pillars’) as central for AI to be trustworthy: Respect for Human Autonomy, Prevention of Harm, Fairness, and Explicability. The Guidelines characterize seven central requirements that are closely related to and building on the ethical principles: 1) human agency and oversight, 2) technical robustness and safety, 3) privacy and data governance, 4) transparency, 5) diversity, non-discrimination and fairness, 6) societal and environmental wellbeing, 7) accountability. The requirements are a mezzo-level component of the framework, connecting the abstract ethical principles with their application to practice. The Ethics Guidelines provides some conceptual reflection on the seven requirements and their various aspects, supporting translation and understanding of the principles in AI development. Furthermore, a self-assessment list is provided with the intent to support operationalizing trustworthy AI (High-Level Expert Group on Artificial Intelligence, 2020). It is explicitly recognized that there may be tensions between these principles and requirements, that need to be attenuated or resolved in the respective AI context.

While the Ethics Guidelines for Trustworthy AI provide a valuable conceptual framework, they are positioned generally with no direct connections to types of AI tools, domains, or areas of applications. Further, trustworthiness has been noted to be a concept conferred to humans and that technology ought to be conceived as reliable, not trustworthy (Freiman, 2022). Thus, AI ethics should reconceive the place of social justice relative to trust and distrust in the power structures associated with AI (Freiman, 2022). Nevertheless, the trustworthy AI approach is influential. The Ethics Guidelines, for example, is foundational for the proposed European Artificial Intelligence Act (European Commission, 2021; Mökander, Axente, et al., 2022). Moreover, the Ethics Guidelines serve as the ethical framework by which the Z-Inspection® Process is grounded.

The Z-Inspection® Process

The Z-Inspection® initiative has developed a method for assessing trustworthy AI within use context (Z-Inspection, 2020). Whereas the Ethics Guidelines outlines static principles, the Z-Inspection® Process is intended to address this limitation, in addition to providing validation of claims made of a system. As a holistic approach, teams of experts are assembled to consider ethical, technical, legal, and domain-specific considerations while developing sociotechnical scenarios and considering the context of the system’s use. Moreover, the process can be applied at any stage of the system’s life cycle, from design to monitoring.

The process is composed of several steps. To bring together a broad spectrum of stakeholders, an interdisciplinary group of researchers from various countries work together to analyze the use context of specific AI tools (Zicari, et al., 2022). Once assembled, the teams define context and boundaries of the assessment relative to the system, create and maintain a log of the steps taken and relevant information through the duration of the process and begin to define sociotechnical scenarios of the system’s use. These involve the various people involved in developing, deploying, and using the AI tool, and their expectations and aims. Additionally, an evidence base is developed, for example, through scholarly and empirical literature among other sources. The scenarios support understanding and analysis of the system’s aims, the relevant actors, their expectations and interactions with the system, processes of the system’s use, and the broader ecosystem in which the system is embedded and operates. From these scenarios and their initial analytical focus, the teams then identify and build consensus around the ethical issues and their tensions. Next, the ethical issues are mapped to the ethical principles and requirements outlined by the Ethics Guidelines for Trustworthy AI, moving from the use of natural language (“open vocabulary”) to the terms used by the Guidelines as a controlled vocabulary (“closed vocabulary”). The mapped issues are then ranked by relevance within context. If necessary, working groups are formed to analyze certain questions or contexts in more detail, for example a technical working group, a domain-specific working group, or a legal working group. From analysis, teams produce a report outlining recommendations on how to address identified ethical tensions, where resolutions are and are not possible, and feedback to relevant stakeholders of the AI system for further development, appropriate use, and ability to redress issues. This is a highly collaborative, co-design process with the aim to produce actionable insights from ethical analysis to inform design or further development (Zicari, Ahmed, et al., 2021; Zicari, Brodersen, et al., 2021; Zicari, Brusseau, et al., 2021; Allahabadi, et al., 2022). The Z-Inspection® Process can therefore be understood as a form of applied research whose aim is to translate findings into practice. The design of the process relies on broad, interdisciplinary collaboration while sensitive to context of use of AI systems. The guiding mechanism of the process, however, is the EU’s Ethics Guidelines. The design of the process suggests both usefulness of application in other jurisdictions and the potential to use a similar ethical framework as a guiding
mechanism for analysis. Thus, it is key to assess compatibility of potential alternative ethical frameworks to assess alignment with the process and its analytical approach.

**The United States’ Blueprint for an AI Bill of Rights**

The Blueprint for an AI Bill of Rights is a white paper published by the White House Office of Science and Technology Policy in October 2022, three years after its European counterpart (White House Office of Science and Technology Policy, 2022). It outlines a framework of five principles and associated practices to inform the design, development, and use of automated systems, such as AI. Developed in consultation with the American public, domain experts, and international input, these five principles express national values intended to guide the development and deployment of systems that are “aligned with democratic values and protect civil rights, civil liberties, and privacy” (p. 4). These principles are: Safe and effective systems; Algorithmic discrimination protections; Data privacy; Notice and explanation; and Human alterations, consideration, and fallback. Each principle is accompanied by an explanation of meaning, including intended provisions and processes. For example, the principle Algorithmic discrimination protections states: “Independent evaluation and plain language reporting in the form of an algorithmic impact assessment… should be performed and made public whenever possible to confirm these protections” (p. 5). It is notable that each principle begins with a summary statement of the core idea of the principle framed as a right, addressing the American public directly. Returning to Algorithmic discrimination protections: “You should not face discrimination by algorithms and systems should be used and designed in an equitable way” (p. 5). The Blueprint also includes a technical companion, outlining expectations of systems relative to principle and how principles can be realized in practice. It is tended for public and private organizations of varying sizes and provides “concrete steps” toward their application, including using preexisting legal frameworks as templates to curb harm or relevant industry best practices (p. 21). The Blueprint is unique among its global counter parts for its emphasis on community-level equity (Hine & Floridi, 2023).

There are, however, two important limitations. First, some of the provisions may be unattainable. As Hine and Floridi (2023) note: “It is unclear what “fully transparent” means, and many algorithms that rely on machine learning are inherently inscrutable.” Second, a key limitation is the non-binding nature of the document, noted by researchers and policy organizations alike (Hine & Floridi, 2023; Lee & Malamud, 2022). Without substantive legislation to support and enact the principles, they remain voluntary guidelines. Similarly, it has been noted that AI ethics is “useless” when abstract principles contribute little to practice (Munn, 2022). Moreover, modern concerns of bias vis-à-vis intersectionalities and structural power dynamics in the public and private sectors must be considered when enacting AI justice. The Z-Inspection® Process potentially offers a method in the US context to apply ethical principles to AI practice. The Blueprint for an AI Bill of Rights is an expression of US ethical guidelines for the responsible development of AI. Therefore, the Blueprint must first be assessed to understand its potential relevance and compatibility within a process predicated on an ethical framework for practice-oriented analysis.

**Previous Comparative Analyses**

Previous work demonstrates varying degrees of scope and specificity. Global approaches looked to map the AI governance landscape (Schmitt 2022) or global policy trends (Ulincanne et al, 2022). Comparative analysis will often focus on groups of actors, such as investigated the use of AI for social responsibility as outlined by Russian, Chinese, and US strategies (Saveliev et al, 2020). Roy and Sreedhar (2022) focus on China, EU, and US AI development and regulation, arguing the EU ought to lead a transatlantic effort. They noted “specific differences in the ethics and values are yet to be explored” between the EU and US (p. 85). Dixon (2022) similarly analyzed Chinese, EU, and US AI governance, including ethical “AI principles.” While substantively engaging with these principles, emphasis is on policy perspectives drawing on the US’ Guidance for Regulation of Artificial Intelligence Applications (Vought, 2020) document. Others have approached comparative analysis of China and the US governing AI documents using quantitative analysis, without a comparative focus on ethical principles (Heine & Floridi, 2022). Mökander, Juneja, et al. (2022) argued the US Algorithmic Accountability Act 2022 could be strengthened by looking to and the proposed EU AI Act, omitting ethical analysis. As the US AI Bill of Rights is relatively new, it is not as represented in the literature, including the above. There is also a lack of analytical focus on ethical comparative analysis of principles underpinning proposed AI regulation.

**RESEARCH QUESTIONS**

1. What are the similarities between the ethical principles expressed in the European Union’s Ethics Guidelines for Trustworthy AI and the United States’ Blueprint for an AI Bill of Rights?
2. Can the Blueprint for an AI Bill of Rights be used as the ethical framework to guide the Z-Inspection® Process in the United States’ context?
3. If so, what are preliminary considerations for required modifications to the Z-Inspection® Process?
METHODOLOGY
This study used qualitative content analysis (Zhang & Wildemuth, 2009). The aim was to condense each set of data into categories to understand how the data sets were similar and how they differed. Assessing similarities and differences was crucial to understand compatibility within the Z-Inspection framework and American and European ethical alignment vis-à-vis potential AI regulation. The data set comprised only of the US’ five principles (White House Office of Science and Technology Policy, 2022) and the EU’s four principles (also called ‘pillars’) (High-Level Expert Group on AI, 2019) within respective documents. Each author began by independently reading over each set of principles, remaining open to the data. Upon initial reading, each author developed an initial set of categories and noted that all but one principle had an analog in its counterpart document. For example, the EU principle number 2 corresponded with US principle number 1. The authors then met to discuss their arrangement of analog principles and confirm categories arising from the data. After building consensus, the authors then independently coded according to the categories: Shared aspects, EU only aspects, US only aspects.

Each author adopted similar processes for coding. The first author used Excel to arrange data, creating individual tabs for each category. For example, using the following fields within individual columns within the “Shared” category: EU Principle; EU Quotation; US Principle; US Quotation; Rationale; Notes. For the category of “EU only aspects” (similarly with US only aspects): EU Principle; EU Quotation; Corresponding; US Principle; Notes. The second author used Word to arrange data, creating one document for the above three categories, arranging them by heading. Under each category heading, the respective principles and their quotations were noted together. After coding, the authors reviewed each code and quotation, discussed their reasoning, and built consensus where possible. Among all of the codes, there were only two instances where the authors made note that their interpretations differed to a substantive degree. Due to the size of the dataset, the authors were able to review coding for all categories. Moreover, the authors were able to review each individual sentence or sentences constituting the quotation which related to both its category and counterpart quotation to assure coherence and consistency between the two. Unit of analysis was themes, typically associated with some ethical principle or what was shared between the two jurisdictions or what was unique to respective jurisdictions. Themes of what was being expressed within increments of the principles were isolated and, where appropriate, either joined with its analog in the “Shared” category or arranged within the respective “only” categories. Concurrently, those aspects which could not be mapped to an analog were noted in their respective “only” categories. This paper only reports on the results of analyzing the Shared aspects category.

FINDINGS
Principle Analogs
Analysis revealed that four principles outlined in respective documents were analogs and expressed a primary ethical concept. The core theme(s) being discussed within the principles shared substantive aspects, while being expressed differently. For example, the EU principle Prevention of harm and the US principle Safe & effective systems primarily express how systems should be designed and deployed to maintain the safety of people, and thus motivated by protecting people from potential harms caused by automated systems such as AI. In most instances, the first sentence of each principle’s explanation acts to declare its fundamental meaning, while further elaboration is provided to clarify or extend scope within respective jurisdictions and traditions. In this example, the first sentences are as follows: Prevention of harm (EU): “AI systems should neither cause nor exacerbate harm or otherwise adversely affect human beings”; and Safe & effective systems (US): “You should be protected from unsafe or ineffective systems.” Both principles invoke safety and protection as their primary concept. Sharing a primary ethical concept thus evidenced analog arrangement and further comparative analysis. Table 1 shows principle analog arrangement and the linking primary ethical concept.

Table 1. Principle analog arrangement and the linking primary ethical concept

Note, however, that the US principle Data Privacy has no direct analog within these frameworks. This principle states “You should be protected from abusive data practices bias built-in protections and you should have agency
over how data about you is used. You should be protected from violations of privacy through design choices that ensure such protections are included by default, including ensuring that data collection conforms to reasonable expectations and that only data strictly necessary for the specific context is collected” (White House Office of Science and Technology Policy, 2022). The EU’s General Data Protection Regulation (GDPR), enacted in 2018, created regulation for the processing and movement of personal data. The law “protects fundamental rights and freedoms of natural persons and in particular their right to the protection of personal data” (European Union, 2023). In the European Guidelines for Trustworthy AI, issues related to data privacy are not addressed on the level of ethical pillars, but on the level of requirements. The US principle of Data Privacy was therefore excluded from comparative analysis of principles, as its analog is already enacted regulation and thus falls out of scope. Along with the GDPR, however, the primary ethical concept represented is privacy and therefore can be regarded conceptually as the additional primary ethical concept constituting the principles undergirding trustworthy AI regulation. Such privacy protections are required and must be accounted for in systems development in the EU or for use in the EU.

**Shared Aspects**

Each of the principles were analyzed for their shared themes relative to their analog. This analysis aimed to understand better the nature and extent of shared ethical underpinnings and associated themes between the US and EU. Below we offer a principle-by-principle discussion arranged by shared primary ethical concepts.

**Protection/Safety**

Themes of protection, safety, and averting potential harm of systems or their use to cause such harm are evidence in respective a and b statements (Table 2). The US quotation states that systems should be designed to proactively protect, while the EU quotation broadly states “not open to malicious use.” The US principle elaborates to qualify protection design via harms “from unintended, yet foreseeable, uses.” Statements c similarly acknowledge the role of “vulnerable” or “diverse communities” in the development of such systems. These statements indicate an expanded role for marginalized communities in creating the technological future.

</tr>
</tbody>
</table>

**Table 2. Quotes of shared aspects of EU Prevention of harm and US Safe & effective systems**

The authors also agreed that another corresponding set of quotations were shared between the principles. However, the authors provided different analytic accounts to support this coding. The authors discussed this part of the dataset at length and while they could agree on the category coding, consensus required acknowledging differing perspectives. These sections are: EU: “AI systems and the environments in which they operate must be safe and secure”; and US: “They should be designed to proactively protect you from harms stemming from unintended, yet foreseeable, uses or impacts of automated systems.” These sections are closely related to the previous sections, and provide further qualification and contextualization of safety, protection, and avoiding harm. The EU stresses safe, secure systems and environments in which they operate, linked to protection-by-design the US suggests. The point of difference, however, focused on the term and use of “environment.” This can be understood as focusing on the AI tool and on the broader context in which the AI tool operates. In this interpretation, the use of the term “environment” suggests organizational, institutional, professional, and similar settings of the human-made world. In contrast, the US principle focuses on the AI tool itself without explicitly mentioning the environment in which it operates. The EU principle, however, qualifies environment: “Preventing harm also entails consideration of the natural environment and all living beings.” Thus, the use of the term “environment” is ambiguous depending on interpretation.
**Explainability**

Respective principles indicate the relevance of explicability/explainability for AI yet collocate this specific theme with different emphasis for importance. The EU indicates user trust in system, while the US indicates notice that such systems are in use and concisely states “understand how and why it contributes to outcomes”, in which the EU elaborates. The US continues with "impacting you", directly indicating individual citizen/right. The US is comparatively more specific. Both, however, discuss informing those impacted, if not the public at large (EU: technically valid, meaningful, useful, and calibrated to level or risk). Both share the idea that explainability may take on different linguistic form relative to context. While the EU appears to use one word (explicability) to convey this specific key functionality changes, while the US “people impacted by the system should be notified of significant use case or key functionality changes.” While the US indicates “generally accessible plain language documentation; notice such systems are in use, notices kept up-to-date). The US, however, includes “notice” whereas the EU does not. While the EU notes systems should be explainable, the US goes on to define this concept for its uses. The EU mentions “those directly and indirectly affected”, while the US “people impacted by the system should be notified of significant use case or key functionality changes.” While the US indicates “generally accessible plain language documentation; it does not go so far as to say for those “directly and indirectly affected”, and these groups of people in the US context appear to also be accorded with changes in functionality and “significant use case changes”, signaling the US couples (public) notice with explainability as concepts in this document.

Similarly, the US suggests a distributed responsibility with “Designers, developers, and deployers.” The US ends with reiterating their definition of explainability as it relates to the citizen, and includes when AI systems are “not the sole input determining the outcome” as a part of explainability, reflecting a kind of 'human-in-the-loop' in notice features. Both refer to explainability within context, and both indicate level of risk (EU: severity of consequences; US: level or risk). The EU indicates explicability is by “degree”, whereas the US links explainability to being technically valid, meaningful, useful, and calibrated to level or risk. Both share the idea that explainability may take on different linguistic form relative to context. While the EU appears to use one word (explicability) to convey several ideas, the US delineates among three components: technically valid, meaningful/useful, calibrated.

</tr>
<tr>
<td>2. “This means that processes need to be transparent, that capabilities and purpose of AI systems openly communicated, and decisions - to the extent possible - explainable to those directly and indirectly affected.”</td>
<td>2. “Designers, developers, and deployers of automated systems should provide generally accessible plain language documentation including clear descriptions of the overall system functioning and the role automation plays, notice that such systems are in use, the individual or organization responsible for the system, and explanations of outcomes that are clear, timely, and accessible. Such notices should be kept up-to-date and people impacted by the systems should be notified of significant use case or key functionality changes. You should know how and why an outcome impacting you was determined by an automated system, including when the automated system is not the sole input determining the outcome.”</td>
</tr>
<tr>
<td>3. “The degree to which explicability is needed is highly dependent on the context and the severity of the consequences if that output is erroneous or otherwise inaccurate.”</td>
<td>3. “Automated systems should provide explanations that are technically valid, meaningful and useful to you and any operators or others who need to understand the system, and calibrated to the level of risk based on the context.”</td>
</tr>
</tbody>
</table>

| Table 3. Quotes of shared aspects of EU Explicability and US Notice & Explanation |

**Justice**

The EU address ‘fairness’ directly, while the US through an inverted framing of “not face discrimination” and “systems should be designed in an equitable way.” The EU indicates concepts of fairness, that they are so inherent they are implied to have commitments to these related principles, and be involved in the development of these systems: these include justice, beneficence, and avoiding “unfair” bias to people and groups. The US, however, defines discrimination within its legal context, listing groups of protected people/groups/attributes under the law. This contrasts with a broader conceptualization of principles. The US also uses “unjustified different treatment”, similar to the EU’s “unfair bias, discrimination, and stigmatization.” Both suggest there are allowable instances of
such bias in systems. While different avenues into a shared concept (EU: fairness, US: discrimination avoidance),
the shared focus is on protection of people/groups.

Both principles indicate that those responsible for AI in some way have certain duties toward its design and
deployment regarding fairness and its impact on people. The EU focuses on proportionate means and ends, and
balancing various interests. The US focuses on protection of individuals and communities and equitable design.
Equitable design could be interpreted to be related to balancing “means and ends”, e.g., means of development with
proportional impacts of ends, however the use of “equitable” explicitly signals a specific view on development,
which is not mentioned by the EU. The EU uses “equal”, while the US uses “equitable”: this is an important
distinction, as it lays out differing ethical priorities of AI development and use, and where equity requires a more
nuanced understanding of communities, their societal positioning relative to protections, harms, and discrimination,
and thus how this can be accounted for in development and use of AI.

<tr>
<td>1. “The development, deployment and use of AI systems must be fair.”</td>
<td>1. “You should not face discrimination by algorithms and systems should be used and designed in an equitable way.”</td>
</tr>
<tr>
<td>2. “The substantive dimension implies a commitment to: ensuring equal and just distribution of both benefits and costs, and ensuring that individuals and groups are free from unfair bias, discrimination and stigmatisation.”</td>
<td>2. “Algorithmic discrimination occurs when automated systems contribute to unjustified different treatment or impacts disfavoring people based on their race, color, ethnicity, sex (including pregnancy, childbirth, and related medical conditions, gender identity, intersex status, and sexual orientation), religion, age, national origin, disability, veteran status, genetic information, or any other classification protected by law.”</td>
</tr>
<tr>
<td>3. “Additionally, fairness implies that AI practitioners should respect the principle of proportionality between means and ends, and consider carefully how to balance competing interests and objectives.”</td>
<td>3. “Designers, developers, and deployers of automated systems should take proactive and continuous measures to protect individuals and communities from algorithmic discrimination and to use and design systems in an equitable way.”</td>
</tr>
</tbody>
</table>

Table 4. Quotes of shared aspects of EU Fairness and US Algorithmic discrimination protections

Comparison of the above principles included a second instance where the authors agreed on category coding, yet
with different analytical accounts for justification. As with the previous instance, while the authors agreed on the
category coding, consensus required acknowledging differing perspectives. These sections are: EU: “Moreover, the
use of AI systems should never lead to people being deceived or unjustifiably impaired in their freedom of choice.”;
and US: “Depending on the specific circumstances, such algorithmic discrimination may violate legal protections.”
The point of difference focused on the use of “freedom of choice” and “legal protections” as parallel concepts in this
context. One interpretation was focused on American economic structures and voting (e.g., who/what can I choose,
when and how?), with an emphasis of freedom of choice as, to some extent, a legal protection. Another
interpretation considered that freedom of choice and individual autonomy can be infringed despite no legal
infringements, possibly arising from algorithms, miscommunication, or deception. Even if not legally relevant, these
may have significant negative implications.

Human autonomy
Both principles are fundamentally concerned with human autonomy and maintaining human choice in an
increasingly automated context. Both signal that systems should be designed around the human and not the reverse.
Similarly, both suggest human-in-the-loop design principles in outlining the degree human participation should be
involved in design, use, and remediation. Respective b quotations mention the impacts of AI on labor. The EU states
such systems should support humans in undertaking work with an aim to create “meaningful work.” The US,
however, indicates “sensitive domains” and the use of systems in these domains should be purpose built with the
ability for oversight and incorporation of human action. The US provides a more detailed qualification of both
maintaining human choice vis-à-vis systems and their impact on labor domains. The EU, however, frames these
same topics broadly.

DISCUSSION

The similarities between the EU and US ethical principles are robust. When including privacy as the primary ethical concept between the US principle Data Privacy and the GDPR, the following are the ethical notions two major jurisdictions are drawing on to guide policy and regulation of AI: Protection/Safety; Explainability; Justice; Human autonomy; and Privacy. Four of the five US principles have a corresponding European analog, underpinned by a primary ethical concept. This finding suggests the use of the US Blueprint for an AI Bill of Rights would make a viable ethical framework as the guiding mechanism for the use of the Z-Inspection® Process in the US context. As mentioned previously, it is important to note that the analog to the US ethical principle Data Privacy appears to be addressed by the GDPR in Europe. This finding indicates that in the developmental and regulatory landscape, the EU already affords these protections. The GDPR therefore provides legal expectations that AI systems developed in the EU or for use within the EU will comply with these protections and strengthens European ethical AI development. Moreover, adaptation of the Z-Inspection® Process in the US context would also suggest data privacy as a perennial ethical issue without a US counterpart to the GDPR or substantive AI regulation predicated on the Blueprint for an AI Bill of Rights. While the seven requirements are an important elaboration of and addition to the four EU principles, the US document does not provide a similar level of granularity in this way. Rather, the US approach emphasizes direct practical application through its Technical Companion. The Technical Companion provides expectations of systems within the context of each principle and often identifies existing laws, regulations, and industry approaches as examples by which to enact the principles. This approach, however, provides no indication of assessment or oversight and remains voluntary. Adoption of the Z-Inspection® Process as an AI assessment process in the US context therefore provides rich opportunity for practical application with a compatible ethical framework and evidence of the methods efficacy (e.g., Zicari, Ahmed, et al., 2021; Zicari, Brodersen, et al., 2021; Zicari, Brusseau, et al., 2021; Allahabadi, et al., 2022). Several options are possible.

First, adapt the process, not the frameworks. For the Z-Inspection® Process to be used in additional global and jurisdictional settings, an adaptation of the process itself would be necessary to accommodate respective frameworks. Focus would be on structural changes to the method within respective jurisdictions, largely independent of respective developments. This approach would account for jurisdictional context, affording potential for individual development as necessary. It would be limiting, however, to disregard potential affordances of multi- or international collaboration. Second, use the process with the US principles expressed in the Blueprint. Focus would be minimally on structural changes to the process, with no mezzo-level requirements. The analytical focus would be on the five US principles. However, previous assessment based on the EU Ethics Guidelines for Trustworthy AI has shown that the level of granularity and specificity offered by the seven requirements is very useful, and that the requirements are more closely related to the context of AI tools than the principles alone (e.g., Zicari, Ahmed, et al., 2021; Zicari, Brodersen, et al., 2021; Zicari, Brusseau, et al., 2021; Allahabadi, et al., 2022).

Third, use the process with the US principles expressed in the Blueprint and develop mezzo-level requirements. To achieve a similar level of granularity, a US adaptation could seek to incorporate similar requirements or turn focus to
the Blueprint’s Technical Companion. Such requirements could utilize the rationales and suggested applications pathways provided for each principle in the Companion. Similarly, the principles outlined in Executive Order 13960 on Promoting the Use of Trustworthy Artificial Intelligence in the Federal Government could also be utilized (as cited in White House Office of Science and Technology Policy, 2022, p. 21). These principles are: (a) lawful and respectful of our Nation’s values; (b) purposeful and performance-driven; (c) accurate, reliable, and effective; (d) safe, secure, and resilient; (e) understandable; (f) responsible and traceable; (g) regularly monitored; (h) transparent; and (i) accountable. However, these principles would need to be defined in such a way as to be useful on the mezzo-level to support the application of the high-level principles in the Blueprint. Utilizing the Technical Companion would provide a mezzo-level to ethical analysis grounded in a jurisdiction-specific focus on application. With the Technical Companion’s reliance on pre-existing legal and regulatory standards, its use in a US adaptation would potentially support analysis of where further regulation may be needed.

Fourth, joint development of adaptations or modifications. In view of the striking similarities between the five US principles and the four EU principles (including the GDPR), a promising approach could consist of relevant US and EU stakeholders developing a joint approach together. This group could build on the existing documents and their principles to add granularity relevant to AI tools. This approach holds potential for increased transatlantic scientific collaboration informing an adapted, modified, or revised version of the Z-Inspection® Process. Joint developmental efforts would support an alignment of AI assessment through the Z-Inspection® Process. This approach could also yield a more generalized assessment method.

Such an adaptation could prove useful both to the US and EU frameworks. The US Blueprint explicitly mentions diverse communities in developmental efforts (Safe & effective systems), equity and historically excluded and legally protected groups (Algorithmic discrimination protections), and sensitive domains of use (Human alterations, consideration, & fallback). Inclusion of these themes at a higher level suggests potential to incorporate concepts of economic and technological justice, intersectionality, and the societal and contextual structures which provide affordances and limitations to equity and justice (Munn, 2022). In the EU approach, these aspects are discussed in the Requirement of Diversity, non-discrimination and fairness. In a US approach, themes of equity and inclusion would therefore be central to ethical appraisals of such technologies, thereby beginning the process of enacting AI justice in practice. However, while the US Blueprint addresses diverse communities in several of its principles, there is no explicit diversity category or requirement such that exists in the EU guidelines. A US-based assessment process may therefore benefit from a more diversified ethical framework consistent with the expression of equity and inclusion within the US principles.

Adapting the Z-Inspection® Process for the American context would potentially provide a conducive environment, both in research and praxis, to align and coordinate effort to develop and maintain responsible AI development. The information professions thus have key contributions, as disciplinary focus is often at the intersection of technology, information, and people. Information research is increasingly necessary to inform responsible advanced technologies development and their ethical appraisals. The impact of AI, for example, on information behaviors, practices, professional education, and in practice (e.g., Cox, 2023; Huang, Samek, & Shiri, 2021) is increasingly prompting relevant new questions as developments continue at a rapid pace. Adaptation of the Z-Inspection® Process in the US context, utilizing the Blueprint for an AI Bill of Rights as its ethical and analytical mechanism provides rich opportunity for information research to follow new lines of inquiry, particularly focused on applied research. Adaptation of this process also creates opportunities for information researchers and practitioners to contribute unique disciplinary perspectives on ethical appraisals of developing technologies alongside experts in other domains of research and practice. Indeed, professional duty and ethics in modern and future information environments may require active participation in ethical appraisals of advanced socio-technical information systems and preparing practitioners for this same.

**CONCLUSION**

The European Union is a leader in its ethical vision for AI, while the United States’ recent addition to the global landscape of ethical principles for AI development contributes a unique vision for equity in AI assessment. The striking similarities between the respective principles suggests the Blueprint for an AI Bill of Rights would make a viable alternative ethical framework underpinning the Z-Inspection® Process. Modifications, however, would be necessary, particularly focused on the mezzo-level within the process, such as the EU’s seven requirements fulfill. Moreover, a joint developmental approach between US and EU stakeholders for further modification of the Z-Inspection® Process for US use presents a unique opportunity for modification and could be a model for an EU-US joint assessment approach. Information research would additionally have unique contributions to make in any of these efforts, as disciplinary focus lies at the intersection of technology, information, and people. Future research should analyze the comparative differences between the frameworks for a more robust understanding of specific adaptations that would need to be developed. Future research could also consider a viable mezzo-level for the US, such as the EU counterpart of the seven requirements.

Data Flourishing: Developing Human-Centered Data Science through Communities of Ethical Practice

Poole, Alex H. 
Drexel University, USA | ahp56@drexel.edu

ABSTRACT
Data Science is a burgeoning area in the iField. But Data Science practices have far outstripped the field’s ethical safeguards. We argue that Data Science graduate education programs must address this critical problem. In this theoretical and conceptual paper, we posit an ordinary macroethics that we call data flourishing. We contend that this macroethics is most appropriately developed through a holistic, human-centered data science (HCDS)-based pedagogy that concentrates on cultivating communities of ethical practice (COEPs) through social learning. We favor embedding this macroethics throughout iField programs’ graduate data science curricula and by extension, the entire data science education enterprise. This paper aligns with the 2023 ASIS&T annual meeting theme of translating research into practice, particularly the subthemes of “improving decision-making” and “understanding the power of information to develop human happiness, equality, and wellbeing.”

KEYWORDS
Ethics; data science; data science education; pedagogy; communities of practice

INTRODUCTION
Data science (DS) work constitutes an ethical minefield. Ethics remains far from embedded in the graduate DS curriculum, however. Scholars have proposed human-centered data science (HCDS) to deal with ethical challenges, which is a positive but insufficient development. DS instead demands an ordinary macroethical foundation that promotes what we call data flourishing (eudaimonia). We argue that this foundation is most appropriately developed through a holistic, human-centered data science (HCDS)-rooted pedagogy that centers on cultivating communities of ethical practice (COEPs) through social learning. We advocate embedding this principle throughout iField programs’ graduate data science curricula and by extension, throughout the entire data science education enterprise.

This conceptual paper first discusses and contextualizes Big Data and data science. Next, we explore algorithms and their implications for data science work, which funnels into the need for HCDS. Third, we describe fruitful HCDS approaches. We broach data ethics fourth. Fifth, graduate data science education is addressed; we then suggest the usefulness of a communities of practice (COPs) model for teaching an HCDS-based ordinary macroethics to promote data flourishing. We conclude with implications for practice and research.

THE APOTHEOSIS OF BIG DATA—AND DATA SCIENCE
Boasting volume, variety, velocity, value, and (ostensibly) veracity, Big Data work capitalizes on probabilities generated through well-nigh labyrinthine mathematical operations (Mayer-Schönberger & Cukier, 2013). However incomplete, Big Data may be wrangled to enable tabulation, aggregation, and analysis—i.e. datafied (Mayer-Schönberger & Cukier, 2013). Datafication putatively enables more sophisticated discernment of patterns or correlations; it involves knowing what, not necessarily why (Mai, 2016; Mayer-Schönberger & Cukier, 2013; Zwitter, 2014).

Big Data work exploits trace data, which emanates from social media, financial transactions, and public transportation use; such data purportedly represents individuals’ actions, not their claims (boyd & Crawford, 2012; K. Davis & Patterson, 2012; Gitelman & Jackson, 2013; Kogan et al., 2020; Leavitt, 2016; Mayer-Schönberger & Cukier, 2013; Zwitter, 2014). Individuals reveal such personal information consciously or unconsciously, willingly or unwillingly, through their prosaic activities (e.g. social media data, health tracking data, emails, text messages, search engines) (Brower, 2013; Mai, 2016; McAfee & Brynjolfsson, 2012; Zwitter, 2014). “Every login, every page view, and every click leaves a trace” (Gillespie, 2014, p. 170); individuals therefore seem merely the aggregate of their social relationships, online interactions, and connections with content (Mayer-Schönberger & Cukier, 2013, p. 157). What is more, service providers entice individuals to volunteer personal information under the auspices of often specious self-empowerment (Brower, 2013; Gillespie, 2014). These providers advance an insidious argument: the more personal information they glean from their users, the better services they can offer (Mai, 2016). This enables the commodification of nearly any banal action.

Big Data elicited a superabundance of hype, appearing the “next frontier for innovation, competition, and productivity” to McKinsey and Company (Manyika et al., 2011). In alluring policy terms, it hinted at more effective medical treatments, more efficient energy use, and individually tailored educational curricula (Big Data Senior Steering Group, Subcommittee on Networking and Information Technology Research and Development, 2016; Executive Office of the President, 2014). At their most hubristic, its advocates warned to technochauvinism, the
notion that computing technology’s alleged objectivity and neutrality represents an effective panacea (Broussard, 2018).

Coincident with Big Data’s rise, data science emerged as both a field of study and a practice that surfaced the collection, preparation, processing, analysis, visualization, storage, management, and preservation of Big Data to construct new insights (Shah, 2020; Stanton, 2012; Wu et al., 2022). The unduly hyped role of data scientist, “a hybrid of data hacker, analyst, communicator, and trusted adviser,” soon followed (Davenport & Patil, 2012, p. 73).

**ALGORITHMS AND THEIR DISCONTENTS**

Even as Big Data’s apostles lauded its potential, others adopted a more cautious if not skeptical tone. Big Data swamped current social, political, and legal institutions; Lazer et al. (2014) warned of “Big data hubris”—the conceit that Big Data supplants conventional data practices (e.g., validity and reliability). Some scholars worried about potential harm from (mis)interpretation and bias as well as from unintended consequences (Bollier, 2010; K. Davis & Patterson, 2012; Metcalf et al., 2016). Key concerns centered on algorithmic opacity and interpretability, objectivity and neutrality, bias and discrimination, agency and accountability, and ownership, rights, and privacy.

**Opacity and interpretability**

Encoded mathematical rules that specify task execution procedures, algorithms tease out patterns and relationships (Ames, 2018; J. L. Davis et al., 2021; Gillespie, 2014). Ever more complex and autonomous, algorithms drive artificial intelligence and agents, especially those deployed in machine learning (Floridi & Taddeo, 2016).

Algorithms’ legitimacy claims rest upon the shibboleth that they are fair and accurate, impartial and objective, efficient and trustworthy (Gillespie, 2014). Belying these attributes, however, algorithmic outputs in fact remain opaque: they seldom disclose their author’s motives or biases, much less how these affect the algorithm’s design, machinations, or outputs (Executive Office of the President, 2014). As a result of unknown or proprietary inputs or black-boxed tools, opacity characterizes Big Data-driven decisions (Burrell, 2016; Iliadis & Russo, 2016). Opacity invariably excludes individuals from opportunities; it also precludes individuals’ ability to seek redress for invidious algorithmic outputs (Executive Office of the President, 2014; Floridi et al., 2018; Floridi & Taddeo, 2016). What is more, opacity militates against interpretability. The complexity of the models on which high predictive accuracy (and thus high generalizability) depends truncate interpretability, as does representational complexity (Bamman, 2016).

**Objectivity and neutrality**

Big Data’s presumptions of objectivity and neutrality are similarly problematic. Common framings of Big Data connoted transparency, even self-evident truth; by apparently mooting human subjectivity, its advocates inoculated their outputs against challenge (Gillespie, 2014; Tanweer et al., 2016). Some phenomena defy representation, however, and Big Data’s pretensions papered over a fundamental if unsettling truth: all DS workers are designers and interpreters (Big Data Senior Steering Group, Subcommittee on Networking and Information Technology Research and Development, 2016; boyd & Crawford, 2012). In fact, Big Data may suggest spurious patterns, even causations, in the process proving neither neutral nor objective nor beneficent (Bollier, 2010; boyd & Crawford, 2012; Executive Office of the President, 2014, 2016; Noble, 2018; Zwitter, 2014).

**Bias and discrimination**

Since they undergird local and global computational infrastructures, algorithms indelibly imprint individuals’, groups’, and communities’ opportunities in areas such as public sphere participation, hiring and employment practices, business management, credit and loan access, policing, criminal sentencing, and welfare and public resource apportionment (Ames, 2018; Burrell, 2016; J. L. Davis et al., 2021; Eubanks, 2017). Algorithms wield power. They both reflect and augment systemic and structural social, political, and cultural inequities (J. L. Davis et al., 2021), encouraging “a feedback loop of injustice” (Eubanks, 2017, p. 7). Algorithms promote the so-called digital redlining of underrepresented or marginalized groups, which leads to (further) inequitable distribution of resources and services (Blodgett et al., 2022; Executive Office of the President, 2014; Noble, 2018).

**Agency and accountability**

Both opacity and lack of interpretability and misleading claims of objectivity and neutrality complicate assignation of agency and accountability. Big Data-driven decisions involve myriad actions by myriad individuals. This globally distributed morality spawns a “many hands” problem; it forestalls assigning or assuming responsibility for data authorship, ownership, output(s), analysis, or (re)use (Zwitter, 2014). As Metcalf et al. (2019) assert, traditional compliance mechanisms (e.g., codes of ethics, ethics trainings) fasten on personal accountability. This jaundiced propensity, however, absolves institutions and social structures. Obscuring harm and blame—and therefore accountability—the many hands problem upends public trust in data science tools and methods (Bowker, 2013; Executive Office of the President, 2014; Floridi & Taddeo, 2016; Gillespie, 2014; Leonelli, 2016; Mai, 2016).
Ownership, rights, and privacy

Fundamental questions regarding data ownership and rights exacerbate the challenges of agency and accountability (Aragon et al., 2016; K. Davis & Patterson, 2012; Gitelman & Jackson, 2013). Policymakers deferred to physical property-based legal traditions, but these fail to accommodate data trace- or data sharing-based concerns (Fiesler & Brubaker, 2016). Furthermore, as Noble (2018) argues, data protection relies upon a rights-based discourse that foregrounds free speech and expression. But since web content is private property, she explains, an individual can effectively purchase another’s web identity. Suffice to say that policy vacuums abound.

Data ownership and rights are inextricable from privacy concerns. Vitiating the fragile distinction between private and public, online and offline, Big Data torpedoed the notion of informed consent, which hinges on individuals making decisions consciously, rationally, and autonomously. An overwhelming number of consent-based requests channels into cognitive overload, even paralysis (Young, 2016). Indeed, individuals tend to consent reflexively, with often perfunctory understanding, which puts them at an ethical disadvantage (Mai, 2016; Zwitter, 2014).

Big Data also upended privacy mechanisms such as opting out, profile controls, encryption, and de-identification (Big Data Senior Steering Group, Subcommittee on Networking and Information Technology Research and Development, 2016; Executive Office of the President, 2014; Mayer-Schönberger & Cukier, 2013). Privacy is not merely an individual issue, moreover; data scientists must consider potential injury, especially to historically marginalized communities, as well (Young, 2016).

To scholars’ dismay, protecting privacy and leveraging data richness surfaced perhaps insoluble trade-offs (Manyika et al., 2011; McAfee & Brynjolfsson, 2012; Young, 2016). On the one hand, many reputedly anonymized datasets remained re-identifiable through data mining, linking, or merging; breach of privacy could result in discrimination (Floridi & Taddeo, 2016; Leonelli, 2016; Young, 2016). On the other, by obscuring provenance de-identification potentially trammeled data’s utility (Executive Office of the President, 2014).

THE IMPERATIVE FOR A HUMAN-CENTERED DATA SCIENCE (HCDS)

Staring down a proverbial Frankenstein’s monster, scholars in the 2010s gravitated toward a human-centered data science (HCDS). Unadulterated data science approaches neglect social nuances, affective relationships, and ethical or value-driven concerns (Aragon et al., 2016). By contrast, HCDS fuses human-computer interaction (HCI), computer-supported cooperative work (CSCW), human computation, data science, and apprehension of social context(s) to yield potentially unique insights (Aragon et al., 2016; Herman et al., 2020; Kogan et al., 2020). Richness, sociality, relationality, complexity, and contextuality—each of these attributes characterizes HCDS (Kogan et al., 2020; Muller et al., 2020).

Eschewing reductive technical and functional problems and goals, human-centeredness holistically, reflectively, and prosaically foregrounds human values and ethics. Elevating individual and communal social responsibility, human-centeredness focuses on the normative as well as the feasible, thereby nurturing trust between people and technology (The IEEE Global Initiative on Ethics of Autonomous and Intelligent Systems, 2019). HCDS offers a powerful antidote to technochauvinism (Tanweer et al., 2022).

Human-centered data science approaches

Numerous scholars advance fruitful HCDS approaches whether conceptual, methodological, or both, each of which we unpack briefly below and later incorporate in our pedagogical model. Each HCDS approach addresses one or more of the key challenges of opacity and interpretability, objectivity and neutrality, bias and discrimination, agency and accountability, and/or ownership, rights, and privacy. Some approaches such as algorithmic reparations have been suggested by individual scholars; others such as design and research methods have been considerably more developed by multiple scholars across the HCDS arena.

Race Critical Code Studies

Attacking technochauvinism, Benjamin (2019) calls attention to a “New Jim Code”: “the employment of new technologies that reflect and reproduce existing inequities but that are promoted and perceived as more objective or progressive than the discriminatory systems of a previous era” (pp. 5–6). Since historically discriminatory or exclusionary policies and practices produced extant data, and since designers do not work in a vacuum, she clarifies, claims for objectivity or neutrality fall flat. Benjamin (2019) promulgates “race critical code studies” (RCCS) as an overarching approach to counter Jim Code. Profoundly emancipatory, RCCS democratizes data’s design and its application in line with solidarity and justice. An integral part of RCCS, “coded equity audits” should be employed to scrutinize existing and novel technologies alike (Benjamin, 2019, p. 185).

Algorithmic reparation

J.L. Davis and her colleagues (2021) insist on data scientists’ moral responsibility to battle historical and structural inequities. This involves reparations, “historically grounded mechanism[s] by which offending parties symbolically and materially mend wrongdoings enacted against individuals and groups” (J. L. Davis et al., 2021, p. 3).
Specifically, these researchers lobby for data curation- and distributed AI-based algorithmic reparation. Grounded in praxis, interdisciplinary, and sociotechnical, such reparations revolve around the collaborative design, production, and evaluation of equitable, anti-oppressive algorithmic systems. Reparations involve accepting community members as experts and embracing reciprocal engagement and cross-training, accounting for multiple intersectional identity configurations (e.g., race, ethnicity, class, gender), determining what data to collect (or not), and system co-creation with members of the impacted communities. Such systems then remedy intersectional structural inequality through systems auditing, censure of discriminatory outputs, and resource redistribution.

**Data feminism**

Insofar as oppressive, historically rooted power structures and systems imperil human-centered data science work, D'Ignazio and Klein (2020) call for “co-liberation” through intersectional data feminism. Based on feminist activism and critical thought and both a goal and a process, data feminism encompasses pluralism, context, and affect; interrogates power relationships, binaries, and hierarchies; and renders labor visible. As D'Ignazio & Klein (2020) remind us, “Before there are data, there are people—people who offer up their experience to be counted and analyzed, people who perform that counting and analysis, people who visualize the data and promote the findings of any particular project, and people who use the product in the end. There are also, always, people who go uncounted—for better or for worse” (p. 10). Data feminism augurs just, equitable, and livable futures.

**Data Science for Social Good**

Rejecting the shibboleth that sheer efficiency constitutes data science’s ultimate goal, Data Science for Social Good (DSSG) promotes individual and collective well-being through democratized policies and programs that involve diverse community partners (Zegura et al., 2018). Notably, DSSG embraces a logic of care in its iterative data collection, preparation, wrangling, visualization, analysis, and presentation. As a normative feminist moral theory, an ethics of care develops, maintains, and enriches caring relations (Noddings, 2013). It foregrounds interconnection and interdependence, relationality and responsibility for others, elevating empathy, receptivity, responsiveness, trust, mutual concern, and sensitivity to local context(s) (Gilligan, 2003; Held, 2005; Noddings, 1992).

**Critical Data Studies**

Given Big Data’s potential for mischief, Iliadis & Russo (2016) insist on the need for an ecumenical Critical Data Studies (CDS), or “research that interrogate[s] all forms of potentially depoliticized data science and...track[s] the ways in which data are generated, curated, and how they permeate and exert power on all manner of forms of life” (p. 2). Put another way, CDS premises resistance and alternatives to technochauvinism. Located at the juncture of science and technology studies, policy and legal fields, the social sciences, and the humanities, CDS claims that because data is inherently interpretive, it necessarily involves values negotiation and communication (Dalton et al., 2016; Neff et al., 2017). Data, in other words, represents starting, not end, points; therefore data sense-making demands collective reflection and compromise (Neff et al., 2017). CDS concentrates on participatory learning and research for the common good through an appreciation of situated, contextualized daily practices.

**Data empathy**

“Human judgment is not a contaminant that can be removed from data,” Tanweer et al. (2016) contend, “but an inherent ingredient in the construction of data sets, which...establish patterns of inclusion and exclusion.” Given an increasing propensity for collaboration and exploiting data from diverse sources (e.g., academic, non-profit, governmental), they recommend not only embracing, but also harnessing human subjectivity through data empathy. According to Stueber (2019), empathy constitutes “the primary epistemic means for knowing other minds.” It therefore includes “a wide range of psychological capacities that are thought of as being central for constituting humans as social creatures allowing us to know what other people are thinking and feeling, to emotionally engage with them, to share their thoughts and feelings, and to care for their well-being” (Stueber, 2019). Data empathy entails discerning data-related values, intentions, expectations, and practices and determining how they shape data’s meaning and its possible uses.

**Design**

Invariably value-laden and effectively political, design reflects and (re)inscribes possible racial, ethnic, gender, and class biases (Eubanks, 2017; Noble, 2018). Design challenges include understanding and wrangling data, collaborating, and communicating results (Muller et al., 2019). Whether concentrating on potential users, datasets, scenarios, models, prototypes, platforms, or interfaces, design decisions and practices impact free speech, censorship, network neutrality, security, and privacy concerns (Feinberg, 2017a; Shilton, 2016). Therefore, designers must interrogate not only their motivations, but the contexts of their decision making (Feinberg, 2017b). In other words, data science workers bear a moral obligation to grapple with how their decisions impact data creation, discovery, capture, analysis, and curation; system design and use; and policy (Floridi & Taddeo, 2016; Muller et al., 2019; Shilton, 2016).
Scholars call for collaborations or partnerships among data scientists, designers, and community members (Muller et al., 2019; Wettersten & Malmgren, 2018). For example, Girardin and Lathia (2017) mandate partnerships to address the biases engendered by feedback loops. In brief, algorithms first exploit ingested data, then communicate outputs to the individual, ostensibly to enrich her experience. The interaction of algorithm and individual creates new behavioral data, which is then parlayed into retraining the algorithm. This process demands a holistic, translational partnership among designers and data scientists; only such collaboration reveals how the interaction of data, algorithms, and interfaces molds individuals’ experiences (Girardin & Lathia, 2017).

In like mind, Aizenberg and van den Hoven (2020) warn against the “formalism trap,” the tendency in design to sacrifice social issues and contexts for apparent technical solutions (p. 2). Insisting that more automation is not always optimal, they favor participatory design, value sensitive design, and values in design. These approaches center negotiating stakeholders’ value tensions and interdisciplinary communication (Aizenberg & van den Hoven, 2020). Participatory design involving voices from marginalized communities to share in decision-making is particularly fruitful (Zytko et al., 2022).

Unpacking the ways in which design “distributes benefits and burdens, reproduces and/or challenges the matrix of domination (white supremacy, heteropatriarchy, capitalism, ableism, settler colonialism, and other forms of structural inequality),” Costanza-Chock (2020) endorses design justice (p. 23). Design justice, in summary, gives control to those with direct salient lived experience of the conditions being changed.

In effect, the partnerships suggested by scholars such as Costanza-Chock, Aizenberg and van den Hoven, and Girardin and Lathia embrace “equal opportunity by design”: systems that promote fairness even as they obviate discrimination (Executive Office of the President, 2016). Ultimately, human-centered design must infuse algorithm design (Aragon et al., 2016).

Research methods

HCDS shows great promise in enriching data science research methods. According to Metcalf & Crawford (2016), traditional, discipline-specific research regulations exempt projects predicated on extant public data, classifying discrimination (Executive Office of the President, 2016). Ultimately, human-centered design must infuse algorithm design (Aragon et al., 2016; Muller et al., 2016). In HCDS, quantitative and qualitative approaches computationally-generated quantitative data and qualitative, socially-situated approaches (Aragon et al., 2016; Kogan et al., 2020; Muller et al., 2016). In HCDS, quantitative and qualitative approaches are “complementary, mutually reinforcing, and co-constitutive” (Tanweer et al., 2021, p. 3). Scholars such as Brooks et al. (2013), Gluesing et al. (2014), Maddock et al. (2016), and Qazi and Wong (2019) demonstrate the utility of synthesis.

First, Brooks et al. (2013) scaled up human analysis via machine learning; this marriage enabled affect detection in a large international collaborative chat log of astrophysicists. Second, by combining automated data collection and analysis and a localized ethnographic approach, Gluesing et al. (2014) obtained both broad and deep understanding.
of the global diffusion of organizational innovation. Third, Maddock et al. (2016) conducted two productive studies. One analyzed social media rumors concerning the 2013 Boston Marathon bombing to develop automated detection algorithms. The other explored Wikipedia talk and article pages. Qualitative findings informed these researchers’ sampling methods and coding schemes, which in turn helped validate their quantitative findings. Fourth, Qazi and Wong (2019) focused on more effective and efficient extraction and visualization of temporal, spatial and behavioral associations pulled from crime reports’ unstructured data. Integrating individuals’ domain knowledge into machine learning systems’ algorithms alleviated the burden of manual, time-consuming database searches.

In HCDS, mixed methods come together perhaps most fruitfully in ethnography and machine learning. A foundational qualitative method, ethnography involves human researchers-cum-instruments immersing themselves in a natural setting. They conduct sustained observation of a small number of individuals to understand those individuals’ activities and the meanings the latter ascribe to those activities (Dourish, 2014; Rotman et al., 2012). Machine learning, by contrast, applies algorithmic processes to myriad anonymized data points (Leavitt, 2016).

Yet ethnography and machine learning occupy much common ground. Exploratory and iterative, grounded and inductive, both demand interpretation and theory development (Leavitt, 2016; Muller et al., 2016; Yapchaian, 2018). What is more, each research paradigm may profitably inform the other’s sampling, coding, analysis, interpretation, and validation procedures (Kogan et al., 2020; Maddock et al., 2016; Murthy, 2013). On the one hand, ethnography enhances Big Data analysis by establishing ground truth (i.e. external validity), and by enabling thick description (Bjerre-Nielsen & Glavind, 2022). On the other hand, machine learning facilitates ethnographic work, e.g., by identifying aggregate population trends encouraging granular investigation, or by sampling multiple sites to depict a larger phenomenon (Leavitt, 2016; Rotman et al., 2012).

In one case, Geiger and Ribes (2011) shed light on Wikipedia vandalism by fusing participant observation and trace ethnography. Diverse, often automatically generated traces (e.g., transaction logs or conversation transcripts) document events; individuals often employ these traces for coordination and accountability purposes. Researchers may parlay such thin traces into thick description. But ethnography does not necessarily permit researchers to demonstrate these activities’ sociocultural importance, much less their change over time. Ethnography should therefore be combined with other qualitative and quantitative methods, Geiger and Ribes (2011) reasoned, whether archival, interview, survey, or statistical. Like other unobtrusive research techniques, however, trace ethnography gives rise to ethical concerns surrounding privacy and informed consent since users can scarcely imagine how their traces may be datafied for research.

In a second example of an ethnography-machine learning collaboration, Rotman et al. (2012) embraced “extreme” ethnography to analyze online environments featuring preternatural size, scope, and fluidity. Just as applied ethnography seeks understanding of and guides decisions, so does extreme ethnography integrate ethnographic and quantitative methods. Extreme ethnography illuminates novel behavior and nuanced relationships in vast, dynamic networks; this empowers individual voices in tandem with massive structural and interactional data.

Overall, scholarship centering on Race Critical Code Studies, algorithmic reparation, data feminism, Data Science for Social Good, Critical Data Studies, data empathy, design, and research methods shows that HCDS scholars occupy much common terrain. An optimal data science, they reason:

- Eschews technochauvinism.
- Features an intersectional, Rawlsian moral commitment to equity and social justice.
- Orient toward praxis.
- Focuses on quotidian practices and on local context(s) and situatedness.
- Is communicative, participatory, democratic, pluralistic, community-based, relational, collaborative, and collective in nature.
- Surfaces visibility and transparency.
- Appreciates affect.
- Is historically informed, acknowledging past oppressions and their structural and institutional legacies in current data and pledging to forestall new data inequities.

HCDS scholars have done meritorious work in proposing frameworks such as DSSG and exploring the importance of design and research methods in particular. Although these HCDS examples have yet to be coordinated—and in many cases implemented or evaluated—they nonetheless represent useful foundational work that can be parlayed into the macroethics we set forth below.

**DATA ETHICS FOR HUMAN-CENTERED DATA SCIENCE**

HCDS approaches offer vital if inchoate contributions to ethical data science theory and practice. But an optimal HCDS demands not a piecemeal, but rather a full-fledged data ethics—viz., a *macroethics.*
Alarmingly few individuals and teams design the technologies that govern and even transform everyday life globally, technologies that often produce inequity (Floridi & Cowls, 2019). A lack of codes, standards, and laws exacerbates this knowledge deficit, which impacts politics, the legal system, and social services (Zwitter, 2014). Hence a profound need exists for a robust data macroethics. Ideally, Florid and Taddeo (2016) posit, such a macroethics envelops “moral problems related to data (including generation, recording, curation, processing, dissemination, sharing and use), algorithms (including artificial intelligence, artificial agents, machine learning and robots) and corresponding practices (including responsible innovation, programming, hacking and professional codes), in order to formulate and support morally good solutions (e.g. right conducts or right values)” (p. 1).

Given scholars’ insistence on the situatedness and quotidian nature of HCDS, a suitable data macroethics is perforce an ordinary ethics, which stipulates that ethical behavior and humanness are prosaically inextricable (Lambek, 2010). Ordinary ethics engages the “tension between the everydayness of the present and the possibility of a different, better everydayness” (Metcalf et al., 2019, p. 457).

Floridi and Cowls (2019) advance five core principles for an Artificial Intelligence (AI) macroethics, principles that are similarly appropriate for HCDS. These principles include beneficence (e.g., safeguarding human well-being and dignity and sustaining the environment), autonomy (e.g., preserving the human power to decide), justice (e.g., preserving solidarity and avoiding unfairness), explicability (e.g., intelligibility and accountability), and non-maleficence (e.g., privacy and security). This macroethics, properly translated into an ordinary macroethics, is the foundation for data flourishing. It should constitute the core of iField graduate data science education.

**GRADUATE DATA SCIENCE EDUCATION**

As Poole (2021) observes, numerous scholars characterize the iField as an ideal venue for data science pedagogy (Anderson & Parker, 2019; Bishop et al., 2019; Durr, 2020; Greenberg et al., 2017; Han & Zhu, 2017; Marchionini, 2016; Shah et al., 2021; Song & Zhu, 2017; Wang, 2018; Wu et al., 2022; Zhang et al., 2022). Despite the iField’s rich potential, scholars seldom addressed ethics in the 2010s. Many publications neglected the matter altogether (Cao, 2018; Chen et al., 2019; Danyluk et al., 2019; Demchenko et al., 2016, 2017; Dumbill et al., 2013; Durr, 2020; Han & Zhu, 2017; Kim, 2016; Oh et al., 2019; Raj et al., 2019; Tang & Sae-Lim, 2016; Varvel et al., 2012; Wiktorski et al., 2016). Others mentioned it only cursorily (Cao, 2019; Irizarry, 2020; Song & Zhu, 2017). Despite burgeoning iField interest, then, data science curricula in the 2010s remained circumscribed (Ortiz-Repiso et al., 2018; Salz et al., 2018; Si et al., 2013).

There were a few exceptions, however. Metcalf et al. (2016) and Wing et al. (2018) enjoined instructors to integrate ethics throughout their curricula. Wing et al. (2018), for instance, suggested offering a stand-alone ethics course, ensuring ethics pervaded all coursework using real data (e.g., project-based), or weaving ethics into all courses. Under these auspices, Wing et al. (2018) favored covering general principles such as codes of ethics; incorporating case studies such as ethical problems caused by biased data; and balancing ethical concerns with business value. Wing (2019) later urged instructors to consider privacy and ethics during each phase of the data lifecycle.

Some scholars, most notably Wu et al. (2022) and Zhang et al. (2022) have developed data science education models. Though Wu et al. (2020) exhorted data science programs to promote social good, these researchers’ rather facile content analysis of 2,239 Chinese job advertisements showed ethics almost absent. Faced with these findings, they called for “special training” in ethics as “a bottom line” (p. 10). In a similar vein, Wu et al. (2022) conducted a content analysis of 96 graduate DS programs that listed 2,084 courses. Practice and project management courses ranked first (34.98%), followed by data mining, analysis, and modeling (14.88%), library and information science (10.51%), “humans and society” (8.83%), data processing, storage, and management (8.73%), mathematics and statistics (6.14%), and computer science and artificial intelligence (6.09%). Wu et al. (2022) parlayed these results into a four module, supposedly human-centered curriculum. Module 1 concentrated on data-driven methods and techniques (e.g., data collection, processing, and storage; data mining, analysis, and modeling; data visualization; statistical analysis; algorithms and programming languages; and machine learning and artificial intelligence); module 2 homed in on domain knowledge (e.g., from information science, health informatics, and marketing); module 3 addressed legal, moral, and ethical issues (e.g., trust, privacy); and module 4 foregrounded personal traits such as critical thinking and communication skills (e.g., creativity, attention to detail).

Zhang et al. (2022) recycled Wu et al. (2022)’s content analysis of 2,239 Chinese job advertisements as well as the latter’s content analysis of 96 graduate programs’ data science listings. The former then added the American Library Association’s (ALA’s) JobLIST (24,058 advertisements between 2006 and 2018), and Indeed.com job listings in the US (1,312), Germany (519) and the UK (333) (all from 2020). Zhang et al. (2022) also executed a Delphi study with 16 members of the iSchool Data Science Curriculum Committee (iDSCC). This eclectic group ranked key topics as follows: 1) basic programming and data analytics/visualization/interpretation/communication; 2) basic mathematics and statistics/machine learning, namely clustering, classification, and linear regression; 3) critical reflection on DS’s societal and ethical implications—primarily minimizing bias and misuse while maximizing fairness and
transparency; 4) data processing and management work such as cleaning, digitization, preservation, and archiving; 5) evaluation and use of DS tools; 6) project management; 7) data and information literacy (including the odd pairing of digital humanities and bias detection).

On the whole, these iField efforts to craft a truly ethical HCDS pedagogy are promising but underdeveloped. While acknowledged by some scholars and apparent in some guise in these frameworks, ethics are not given appropriate pride of place. In Wu et al.’s (2022) content analysis, for example, ethics ranked fourth, falling under the broad category of “humans and society.” Second, Zhang et al. (2022)’s iDSCC informants ranked ethics only third of seven key topics (though in discussing this ranking, the authors note in a perfunctory non-sequitur that ethics should be integrated across the curriculum). Third, Wu et al.’s (2022) framework includes only a single module that explicitly mentions ethics, which problematizes if not vitiates the authors’ claim to human-centeredness. In fact, Wu et al.’s framework seems vocationally centered, not human-centered. Fourth, frameworks such as Wu et al.’s (2022) and Zhang et al.’s (2022) give scant indication of how ethics fits with other topics in a given module, much less how other modules might incorporate ethics to militate against siloing. Proposed DS education models might be augmented by reframing modules as both/and instead of either/or, and thus mitigating siloing. Fifth, content analysis of job advertisements and to a lesser extent, of graduate programs, underpins these models. Relying on this data is problematic, though. There is no guarantee that what is listed in a job advertisement as a responsibility at one point in time is actually what a worker actually does. Similarly, there is no assurance that courses listed are ultimately offered (and how frequently, for that matter), or that courses offered succeed in inculcating students with the competencies they claim in their titles or descriptions. These scholars also neglect to explain or justify their sampling strategies and decisions. The addition of interview data in Zhang et al. (2022), for instance, is useful but hardly sufficient, especially given the composition of the sample. Last, by drawing so heavily on content analyses, these models focus more on what is and slights what should be—a seeming abdication of pedagogical and certainly of humanistic responsibility. This shortfall is especially striking since some scholars explicitly proclaim the iField’s commitment to normative data science work (e.g. Shah et al., 2021). Sixth and finally, despite their claims of human-centeredness, scholars by and large neglect to incorporate, much less to foreground, germane scholarly literature, including that rooted in HCDS.

Given the manifest gaps and shortcomings of these efforts, we promulgate a new model for data science education (Figure 1). Floridi and Cows’ five principles (beneficence, autonomy, justice, explicability, and non-maleficence) constitute its foundation. We propose five submodules to flesh out these principles. Three align with but go beyond Wu et al. (2022) and Zhang et al. (2022). We add two other submodules based on our extensive analysis of the HCDS literature.

Our first submodule, data skills and practices, generally conforms to Wu et al.’s module 1 (data-driven methods and techniques), which focuses on data collection, processing, and storage; data mining, analysis, and modeling; data visualization; statistical analysis; algorithms and programming languages; and machine learning and artificial intelligence. We augment this module in two ways, however: we add “tool evaluation and use” (pulling from Zhang et al. [2022]), and we replace the archaic “storage” with “curation,” since the latter term more holistically captures the importance of a lifecycle approach that ensures fit for future purpose (Poole, 2016). Second, our domain knowledge submodule extends Wu et al.’s second module by including Library Science (Poole, 2021). Our third submodule addresses soft skills. It includes project management, communication, cultural competence, customer service, adaptability/flexibility, presentation skills, reflective practice, writing skills, teamwork/collaboration, DEI commitment, interpersonal, initiative, problem-solving, outreach, creativity, critical thinking, continuous learning (Lankes et al., 2015; Partridge et al., 2010; Saunders, 2019; Saunders & Bajjaly, 2022). This submodule overlaps with but again markedly enhances Wu et al.’s (2022) third module. Our review of the HCDS literature suggests the need for a fourth submodule, design, and a fifth, research methods. The latter should be anchored in Science and Technology Studies (STS) (e.g. Latour, 1987; Latour & Woolgar, 1986; Van House, 2005).

As shown in Figure 1, under the aegis of a macroethics of data flourishing, each of the proposed modules (beneficence, autonomy, justice, explicability, and non-maleficence) encompasses each submodule (data skills, domain knowledge, soft skills, design, and research methods). In short, we propose a graduate data science education that turns on a holistic, integrative, profoundly humanistic approach. A HCDS-anchored macroethical approach would be most fruitful in instantiating this model; communities of practice (COPs) are an optimal way to do so.

**COMMUNITIES OF ETHICAL PRACTICE (COEPS)**

Communities of practice represent an ideal vehicle for developing an ordinary DS macroethics. Specifically, we propose the development of HCDS-based communities of ethical practice (COEPS) in and across iField graduate data science programs. These COEPS rest on Floridi and Cows’ macroethical principles of beneficence, autonomy, justice, explicability, and non-maleficence. Under the auspices of these principles are data-driven methods and
techniques, domain knowledge, soft skills, design, and research methods. COEPs address the chronic challenges of opacity and interpretability, objectivity and neutrality, agency and accountability, and ownership, rights, and privacy underscored in scholarly literature. At the same time, COEPs enable the integration and as important, the testing, of HCDS approaches such as Race Critical Code Studies, Critical Data Studies, data empathy, data feminism, Data Science for Social Good, data vision, and algorithmic reparations. We next discuss the attributes of communities of practice.

According to Etienne Wenger (2017), learning inheres in human nature (see also Brown et al., 1989; Brown & Duguid, 1991; Lave, 1991; Wenger, 2000, 2006, 2010). Not a special discrete activity, learning is participatory and social; it flourishes when situated in individuals’ prosaic, lived experiences. Wenger’s social theory of learning includes four components.

First and most holistically, social learning involves experiencing life meaningfully. Second, social learning centers on practice. Incorporating the whole person, both knowing and acting, tacit and explicit, practice surfaces the shared historical and social contexts, resources, relationships, and perspectives that underpin common engagement in action. In other words, practice creates structure(s) for and permits meaning to emerge from individual and communal doing. This negotiation of meaning demands continuous and sustained attention, interaction, and (re)adjustment. Participation in these activities revolves around membership in and experience with communities and enterprises. Both personal and social, participation combines talking, feeling, doing, and belonging; it is a prerequisite for identity formation. A key part of meaning-making in practice, reification “giv[es] form to our experience by producing objects that congeal this experience into ‘thingness’” (Wenger, 2017, p. 58). These objects include terms, concepts, stories, symbols, abstractions, and tools. Third, Wenger’s learning theory includes community, the social arrangements that facilitate competent participation. Community creation, consolidation, and perpetuation depends in turn on common understanding of, engagement in, alignment with, and accountability for a shared enterprise over time, which incorporates a shared repertoire—“routines, words, tools, ways of doing things, stories, gestures, symbols, genres, actions, or concepts” (Wenger, 2017, p. 83). Fourth, identity embraces interleaved participation and reification; individual experience and social interpretation inform each other. In sum, learning changes not only our practices and our communities, but also who we are.

To enable social learning in practice, Wenger advocates “legitimate peripheral participation” (LPP). LPP expands the traditional model of apprenticeship from master and student to “one of changing participation and identity transformation in a community of practice” (Wenger, 2017, p. 11). LPP encompasses peripherality and legitimacy. First, peripherality exposes individuals to authentic if approximate full practice. Peripherality incorporates engagement, negotiation, and repertoire, but with lower stakes and augmented support. Second, newcomers must be treated as legitimate potential community members. In sum, COEPs create meaningful practice by developing and leveraging community and identity.

COEPs present a prime opportunity to socialize graduate students into data science work. Although space limitations preclude us from adumbrating curriculum specifics, we make the following modest recommendations. We suggest that programs use authentic public data sets, tackle actual public and private DS ethical dilemmas through case studies, test out conceptual frameworks such as Data Science for Social Good (DSSG) and data feminism, and undertake activities such as algorithmic audits. As part of this socialization, we recommend consistent, prolonged student exposure to practitioners and their real-world work, ideally through an experiential learning component integrated into the curriculum, as well as through research mentoring from DS faculty (especially early career faculty). Ultimately, a COEP-based strategy will enable the development of a truly human-centered data science that supports an ordinary macroethics leading to data flourishing.
CONCLUSION

Data science work is fraught with ethical choices—and challenges. But ethics has been relatively overlooked in the graduate DS curriculum. We advance an ordinary macroethical foundation that promotes what we call data flourishing. This foundation is best developed through a holistic, social, human-centered data science (HCDS)-rooted pedagogy that centers on developing communities of ethical practice (COEPs). We recommend embedding data flourishing in iField programs’ graduate data science curricula and by extension, throughout the data science ecology.

We trust that this paper suggests the rich potential of such a macroethics and redresses the shortcomings of other frameworks. Questions for future research nonetheless abound. First, how might our COEP model be translated into prosaic curriculum materials? What sorts of demos, case studies, readings, exercises, and assignments would prove most useful? Second, how might the proposed model be adapted to undergraduate and/or continuing education? Third, how might different national contexts impact the proposed model? Fourth, who is best equipped to teach data flourishing?

Data flourishing implies data humility. Whether human-centered or not, as Bica (2019) reminds us, data science provides no “silver bullet.”

“Get Our Feet Wet and Hands Dirty”: Black Community-Based Librarianship and the Fight Against Information Poverty, 1940-1975

Poole, Alex H. | Drexel University, USA | ahp56@drexel.edu

ABSTRACT
Focusing on information services to marginalized urban communities in the United States between 1940 and 1975, this paper argues that African American librarians played foundational roles in early community-based librarianship (CBL) initiatives. In doing so, Black librarians skillfully and resourcefully fought information poverty, pushed for social and political equality, and promoted their communities’ well-being through proactive information provision. By fighting the systemic racism throttling inner-city Black communities, their labors constituted a seminal contribution to the post-World War II United States Freedom Struggle. Theirs was a specifically Black CBL. Underpinned by the theoretical work of Elfreda Chatman, this heretofore hidden history offers fruitful lessons for current library and information science practice. It therefore aligns with the annual meeting theme, “Translating Information Research into Practice, Policy, and Action,” particularly its emphasis on “creating effective models of information provision, creating empathetic information services” and on “understanding the power of information to develop human happiness, equality, and wellbeing.”

KEYWORDS
Diversity, equity, and inclusion (DEI); community-based librarianship; social justice; information poverty; information behavior

INTRODUCTION
Recent scholarly literature stresses the rich and diverse possibilities of community engagement work (Bishop et al., 2009; Connaway, 2013; Dali, 2022; Edwards et al., 2013; Kazmer, 2005; Kranich, 2005; Lenstra & D’Arpa, 2019; Loader, 2003; McCook, 2000a, 2000b; Mehra & Robinson, 2009; Mehra & Singh, 2016; Mehra & Srinivasan, 2007; Melaville et al., 2006; Pershing, 2023; Poole, 2021, 2022; Poole et al., 2022; R. Scott, 2011a, 2011b; Singh et al., 2022; Taylor, 1999; Williams & Durrance, 2017; Yoon & Copeland, 2020). Cultivating democratic citizenship by promoting inclusion, belonging, equality, equity, health, and social justice through civic involvement, community engagement work embraces collaborative, participatory activities, community relationship- and capacity-building, community empowerment, and reciprocal learning. It both respects and harmonizes with community values, its history, and the lived experience of its members. This scholarship points to a broader sensitizing concept (Blumer, 1954): what we call community-based librarianship (CBL).

Focusing on diverse, equitable, and empathetic information services to marginalized urban communities in the United States between 1940 and 1975, this paper argues that African American librarians played foundational roles in early CBL initiatives. In doing so, Black librarians skillfully, resourcefully, and tirelessly fought information poverty and promoted their communities’ well-being through proactive information provision. Encouraging community members to see quality, trusted information as a human right, these information professionals experimented with new activities and services and reconfigured familiar ones. Moreover, by fighting the systemic and institutional racism throttling inner-city African American communities, their labor constituted a vital contribution to the post-World War II United States Black Freedom Struggle. Theirs was a specifically Black CBL.

After first explaining our theoretical debts, namely to Elfreda Chatman, we diagram our methods. Then we explore the larger context of librarianship and race in the twentieth-century United States, highlighting the work of Black librarians in the face of both personal and professional racism. Next, we cover the imperative for new approaches to librarianship and new types of information provision that arose from post-1940 political, social, and cultural change. Two exemplary Black CBL initiatives are then broached: one concentrates on the Free Library of Philadelphia, and the other on the San Francisco Public Library. We conclude by discussing the practical and research implications and lessons learned from Black CBL.

INFORMATION POVERTY AND SMALL WORLDS
Information scientist Elfreda Chatman (1991) characterizes an impoverished information world as “one that has a limited range of new possibilities, and…other perceptions about reality are not adequate, trustworthy, and reliable.” Whether by dint of unwillingness or inability, information poor people perceive themselves as lacking access to potentially helpful information sources that address critical worries or concerns; therefore they elect not to seek it (Chatman, 1996).
Often socioeconomically marginalized, information poor people dwell in small worlds based on routine and predictable activities. A small world, Chatman (1999) clarifies, constitutes “a society in which mutual opinions and concerns are reflected by its members, a world in which language and customs bind its participants to a worldview” (p. 213). Supporting a small world, a worldview represents a collective awareness of or a common set of beliefs about social reality, namely what is important, relevant, or trustworthy (Chatman, 1999). Social norms, or collective, customary habits and behavioral codes that supply a sense of direction, normalcy, and order support a worldview (Chatman, 1999). By extension, a small world’s members see normative behavior as contextually appropriate (Chatman, 2000). As a normative construct, finally, information behavior denotes an approach to “everyday reality and its effect on actions to gain or avoid the possession of information” (Chatman, 2000, p. 14).

Chatman’s 1991 study illuminated the worldview of lower working class women of color. On the one hand, they accepted that problematic situations occurred frequently and without warning; on the other, they avoided long-term planning because it seemed to lead only to failure. Seeing themselves as invisible and effectively helpless outsiders, Chatman’s sample sought and used information solely to address immediate, localized, prosaic, practical, and concrete needs, concerns, or problems. These women leveraged information drawn from their personal experience or information conveyed by trusted others; this information’s believability and its alignment with what others saw as commonsensical reality determined its acceptability. Therefore, membership in a particular social group, Chatman (1996) insisted, paradoxically could exacerbate information poverty: one may experience an information need but decline to address it because of self-reliance or skepticism of outsiders. Admission of one’s need may be risky, potentially even dangerous, so information poor people embrace self-protective behaviors such as secrecy and deception to appear normal and to align themselves with locally sanctioned coping behaviors.

Chatman’s subsequent study of incarcerated women found them living a “life in the round” bolstered by a particular worldview featuring common codes and a common language. In this life, most things are both tacitly understood and publicly monitored. Life in the round “permits social meaning to happen,” as “news comes to a small stage” (Chatman, 1999, p. 212). Given their perceived impotence vis-à-vis the large world, these women’s often avoided information because it proved merely a source of stress. They will cross boundaries only if the information is critical and relevant, and their life in the round is no longer functioning (Chatman, 1999).

Chatman’s body of scholarship is especially well-suited to exploring community-based librarianship. As she (1999) explains, “In a community, one’s sense of self becomes clearer because others reflect the shared values of that world. Community in its most intrinsic sense is the most existential definition of who one is. Ultimately this means that the stuff of one’s world is made from such things as social heritage, language, and the myriad of social norms that govern collective behavior” (p. 211).

Numerous scholars offer thought-provoking critiques and extensions of Chatman’s research (e.g. Britz, 2004; Floegel & Costello, 2021; Franklin, 2020; Gibson & Cooke, 2023; Gibson & Martin, 2019; Gray, 2022; Haider & Bawden, 2007; Kitzie, 2021; Lievrouw & Farb, 2005; Marcella & Chowdhury, 2020; Mehra, 2021; Ndumu & Mabi, 2021; Roy & Shiroma, 2021; Yu, 2006; Yu et al., 2016). In this spirit, the work of Black community-based librarians suggests an opportunity to expand Chatman’s definition of information poverty to include not just exigent practical information, but also historical, heritage, cultural, and social information. African American librarians who fought information poverty both provided prosaic life information and encouraged Blacks to see themselves as empowered actors in history, in stories, and in current culture. What is more, these librarians’ story offers a novel opportunity to use Chatman’s work historically, further attesting to its broad utility (Poole, 2020).

Small world life as depicted by Chatman involved not only homes and workplaces, but also third places. According to Oldenburg (1999), third places are inclusive, local, and casual. Third places unite neighborhoods; provide assimilation spaces, sorting areas (bringing together people for first time who later create other forms of association), and staging areas during crises; serve as political and intellectual forums as well as entertainment venues; stimulate generational mixing; and encourage camaraderie, care, belonging, and welfare. Black community-based librarians took advantage of these spaces.

In light of the prevalence of information poverty in Northern urban communities between 1940 and 1975, Black librarians faced a formidable challenge. We focus on how they ameliorated information poverty in libraries, homes, and community spaces.

**METHODS**

According to information scientist Boyd Rayward (1985), “Historical study consists in the discerning of patterns, the imposition of plausible order, the recognition of coherence existing in the superficial chaos of events, circumstances, developments, ideas, and the personal and institutional interactions that create or surround a particular situation” (p. 121). A qualitative method because of its immanently interpretative nature, historical study reconstructs the past to understand events, situations, processes, behaviors, and practices, and to plan for the future; it therefore plays a key...
role in theory development and practice improvement (Pickard, 2013; Rayward, 2004). A lack of history, by contrast, leads to an attenuated sense of identity (Buckland & Hahn, 1998).

Historical study involves six iterative stages (Pickard, 2013). First, we identified a fruitful topic. In doing so, we considered chronological and geographical limits as well as availability of primary and secondary sources. We asked questions such as where, when, who, how, and why. Second, we unearthed a broad range of primary and secondary sources. Third, we collected and interrogated our sources, posing questions such as: Is the source authentic? What is its provenance? Who created it? Was the creator trustworthy and knowledgeable? What did source mean at the time it was created? Fourth, our analysis was iterative. We sought not only to think critically in terms of themes and relationships, but also to be reflexive concerning our own beliefs and values. Fifth, we interpreted our analysis, seeking to develop “empathy with the context” (Pickard, 2013, p. 174). Finally, we wrote up our findings and sought to convey transparency and to establish trustworthiness.

THE UNITED STATES SOCIAL AND POLITICAL CONTEXT

As historian Manning Marable (2006) explains, the Freedom Struggle focused on two often overlapping, seldom mutually exclusive ideals. First, liberal integrationist African Americans sought equality, which entailed “the achievement of full civil and democratic rights under the existing U.S. state and the abolition of all structural barriers based on racial designation” (p. 213). Second was the Black nationalist tradition, which centered on self-determination. Given the United States’s effective denial of citizenship to African Americans, self-determination represented Blacks’ “inalienable right to determine their own future” irrespective of their chosen political institutions (Marable, 2006, p. 214). These two ideals played out in community-based librarianship between 1940 and 1975; Black librarians borrowed from both traditions and the former’s beliefs, values, and information behavior reflected this dual commitment. In fact, these ideals helped them make war on American apartheid, represent and uplift their fellow Black Americans, and implement new models of community-based librarianship in urban neighborhoods.

American apartheid
Sociologists Douglas Massey and Nancy Denton (1994) characterize the early 1940s coalescence of northern urban ghettos as “American apartheid.” The two Great Migrations of African Americans from the south (encompassing 6.5 million souls) beginning in the mid-1910s exacerbated existing northern housing shortages. Federal and local government policies and agencies abetted residential, vocational, and educational racial discrimination, notably in the Federal Housing Act of 1934 and in the practice of redlining more broadly. Residential segregation via restrictive covenants remained until 1948’s Shelley v. Kraemer; two more decades passed before passage of the Fair Housing Act, which in any event lacked enforcement mechanisms. Burgeoning urban populations led to further ghettoization after the Second World War; nearly two-thirds (64%) of the U.S. population lived in cities by 1950. With postwar suburbanization, urban renewal, and white flight, Black urban communities found themselves in a state of unprecedented racialized spatial isolation (Lipsitz, 2011; Massey & Denton, 1994). Thus starved of resources, these communities constituted small worlds in which information poverty and socioeconomic poverty brutally reinforced one another. Exacerbating matters still further, de facto segregation remained rampant even after Brown v. Board of Education (1954), the Civil Rights Act of 1964, and the Voting Rights Act of 1965. A child of the segregated South and later Director of the Phillis Wheatley Community Library in Rochester, New York, James Wright (1972) agonized, “We moved one after the other to many large urban areas in hope of finding a better life. We only met with despair and broken promises from a ‘liberal White’ in the North” (p. 221).

American apartheid marred libraries as well. Most Blacks migrated from locales-cum-small worlds that barred them from libraries or at best provided separate and profoundly unequal services. African Americans also suffered from grossly inadequate and inequitable southern public education (Anderson, 1989). But effectively integrated public library service remained rare in northern cities due to redlining and government machinations; hence many branches served nearly all-Black populations (Wiegand, 2015). Moreover, as a consequence of white flight, the loss of manufacturing jobs, and the decimation of the urban tax base, federal funding proved indispensable to inner-city libraries. In fact, the most vital CBL achievements drew upon monies disbursed during Lyndon Johnson’s administration through the Library Services and Construction Act (LSCA) (1964), which augmented the Library Services Act of 1956, the Economic Opportunity Act (EOA) (1964), and the Higher Education Act of 1965. Building on Franklin D. Roosevelt’s Four Freedoms, Johnson posited a fifth: “freedom from ignorance.” Yet that funding remained subject to the political climate, and once reaction hit the United States in the 1970s (e.g. Kruse & Zelizer, 2019; Patterson, 2005), Black librarians were hard-pressed to continue their CBL work, however diligently they tried.

The Black professional middle class and uplift
Black librarians who pioneered CBL in the cities contributed not only to the profession, but also to the long Freedom Struggle in the 20th century (Hall, 2005; Hine, 2003; Tuck, 2011). Highly educated professionals, they
generally came from families and by extension, from small worlds that embraced classic bourgeois values as normative and that invested deeply in books and libraries as essential vehicles for education and social mobility. “Books and libraries have always been a part of my life,” Vivian Hewitt (1970) remembered. “As a child, my parents read aloud to us at bedtime. When they couldn’t, the older children did. When the older kids went to the public library, which was in walking distance from our house, the younger ones always tagged along. I had a library card as soon as I could write my name” (p. 254). Spencer Shaw (1970) related the seminal influence of his local branch librarian, who ensured a welcoming environment and whose efforts complemented those of Shaw’s family members, who often gave books as presents for special occasions.

Community-based librarians such as Hewitt and Shaw committed to normative behavior centering on uplift. According to historian Kevin Gaines, uplift “represented the struggle for a positive black identity in a deeply racist society, turning the pejorative designation of race into a source of dignity and self-affirmation through an ideology of class differentiation, self-help, and interdependence” (p. 3). At once representing and uplifting the race constituted a formidable “double burden” (Holt, 2011, p. 241). This two-front fight for racial advancement and uplift surfaced social responsibility and community development and leadership (Gatewood, 2000; S. J. Shaw, 2010; Summers, 2004). Due to their political disfranchisement, Black middle class women in particular owned a lengthy history of community uplift work (Gilkes, 1980; Higginbotham, 1993; Lerner, 1979; A. F. Scott, 1990). The National Association of Colored Women (NACW) (established in 1896) epitomized this pledge with their slogan “lifting as we climb.”

This community-centered worldview animated the information behavior of Black community-based librarians whether men or women. In this spirit, St. John’s University’s Mohammed Aman (1972) wondered, “Have we mobilized and deployed our resources in a delivery pattern that is meaningful to our black clients? Are we helping to provide the necessary commitments and leadership to the black community?” (p. 155). Wendell Wray, the first African American man to graduate from the University of Pittsburgh’s School of Library and Information Science, insisted (1977), “the best talent there is must rally to serve the race” (p. 77). Medgar Evers College’s Robert Ford, Jr. (1972) urged Black librarians to embrace social responsibility through community engagement and uplift. “We must be sincerely concerned about the quality of life in the ghetto and the quality of the institutions that serve it,” he maintained. “For better or worse, these are our people and our posterity” (p. 253).

RACE AND LIBRARIANSHIP IN THE UNITED STATES

Librarianship historically either offered separate but unequal or peremptorily refused service to African Americans, concomitantly marginalizing Black librarians (Cresswell, 1996; Du Mont, 1986; Fultz, 2006; Hanbury, 2019; Jackson et al., 2012; Josey, 1994; Josey & Shockley, 1977; Knott, 2016; Knowlton, 2018; Mehra & Gray, 2020; Ndumu & Chancellor, 2021; Poole, 2018; Tucker, 1998; Wiegand & Wiegand, 2018).

As part of normative racial representation and uplift, Black librarians broke new ground professionally, countered stereotypes, and inspired Black and white users alike. Born in 1920, Vivian Hewitt was a trailblazing Black librarian. When she matriculated at the University of Pittsburgh during World War II, she was the only Black person in the library school and one of four Blacks on the entire campus. “I was really trained to be a part of the community,” she (2003) later noted. After completing her MLS in 1944, Hewitt secured a full-time appointment at Wylie Avenue Branch Library as a Junior Assistant and Special Worker with Young Adults—the first African American to be so appointed. “I was to be the Jackie Robinson of the library profession in the city!” she (1972) quipped (p. 258).

The Wiley branch catered to a predominantly African American community of 60,000 people struggling with information poverty and eager for information services. This small world featured the city’s heaviest concentration of social welfare and recreation agencies, ranging from settlement houses to YMCAs to Boys’ Clubs. The branch was as much a social services agency as a library, and staff members such as Hewitt immersed themselves, serving on all types of community committees in the neighborhood. “Count me among the original, aware, ‘I care,’ inner-city librarians!” she (1970) wrote (p. 262).

As a Black librarian, Hewitt felt keenly the pressure of representing the race both professionally and personally. “24 hours a day, I was expected to represent the Library,” she (1970) noted. Indeed, a fundamental part of Hewitt’s CBL work involved self-presentation. She was “‘showcased’ to the hilt—mixed groups, young people and women’s clubs, men’s organizations, health agencies, you name it” (p. 261). Expected to disprove racist stereotypes about Blacks, Hewitt sought to be “the absolute quintessence of the Model Librarian” (p. 261). But such demands paid off; a justifiably proud Hewitt (2003) concluded, “I paved the way for acceptance of others.”

Other librarians felt similar normative pressure as they worked with members of information poor small worlds. Born in 1911 and the first African American Coordinator of Children’s Services at the New York Public Library, Augusta Baker (1970) reflected, “We children’s librarians worked hard to bring children and books together. We
told stories, read aloud, showed fine art, gave concerts. We were dedicated to the cultural growth of our children” (p. 119). For example, since children’s books usually depicted African Americans as “shiftless, happy, grinning, dialect-speaking menials,” Baker established the James Weldon Johnson Memorial Collection of books to ensure awareness of Black heritage and to correct racist distortions of the historical and cultural record (p. 118). “The black child needs the image of a black librarian—and white children need this image also,” she elaborated. “It hasn’t been too long since a class of junior high school white children in New York City thought that ‘all Negroes are drunks’” (p. 123). Embracing the cultural and pleasurable as well as the practical, Baker’s labors epitomized a broad notion of fighting information poverty.

Like other Black community-based librarians, Baker left a substantial legacy (c.f. Baker, 1991). She described her storytelling efforts as “nurturing the spirit-self” and “enriching and deepening a child’s feelings” (Baker & Greene, 1987, p. xii). “I ride the subways and strange young people speak to me, identify themselves as ‘story hour’ children, and then talk eagerly about the influence of the Library on their lives;” she (1970) marveled (p. 120).

Similar to Hewitt and Baker, Spencer Shaw, born in 1916, shattered racial barriers. Appointed the first Black librarian to work at the Hartford, Connecticut, Public Library in 1941, Shaw (1970) wrote sanguinely to library director Truman Temple, “the library can do much in fostering intelligent racial attitudes among the different groups that go to make up the ‘melting pot’ of America” (p. 152). But Shaw’s faith in the American creed was sorely tested. Inducted stateside into a segregated World War II army, he (1970) recalled feeling that he was “reliving the battle of the North and the South.” “On interstate travel,” he explained, “curtains were pulled in dining cars between my table and the rest of the train if I cared to eat. In Georgia, while my fellow white officers lounged in a beautiful Club, their Negro counterparts were restricted to a converted barracks building which we labeled ‘Uncle Tom’s Cabin’” (p. 156). Shaw was even referred to his base’s chaplain after he “questioned too much the inequalities between our stated democratic principles and the practices evident within the military and outside in civilian life” (p. 156).

Even as they rallied up “firsts,” these Black librarians continued to face professional (e.g., hiring and promotion) and personal (e.g., housing) as well as social and political discrimination. The first minority services coordinator for Los Angeles County Public Library, Binnie Tate (1970) felt isolated when attending school and working in New York. “It became terribly frustrating being ‘The One’—the one black student in the class, the one black employee at a library branch, or the one black included in white social affairs” (p. 126). It was small wonder that she wrote, “There will never really be a free library as long as many who work there are not themselves truly free” (p. 129). Nevertheless, Tate and her fellow African American librarians persisted in grappling with information poverty.

The special roles and responsibilities of Black librarians

A shortage of African American librarians helped account for Black communities’ non-use of libraries (Welbourne, Jr., 1970). Director of the Benton Harbor, Michigan, Public Library, Thomas Alford (1972) insisted that Black librarians related to other African Americans far better than did white librarians. In Black neighborhoods, white librarians often failed to tailor their information services to crucial community needs; this high handedness exacerbated existing community suspicions. Like Welbourne, Alford foresaw increased library use should more African American librarians work in Black neighborhoods and accommodate these small worlds’ information behaviors.

Black librarians had special capabilities for working with urban small worlds. Tate (1970) ascribed this to lived experience and Alford (1972) thought Black librarians generally more familiar with “meeting life’s basic needs and dealing with the hard facts of poverty and destitution” (p. 239). This lived experience enhanced their ability not only to serve as curators of Black history and heritage, but also to develop nontraditional library services and otherwise make the library a key presence in community life (Aman, 1972). A veteran like Shaw of the segregated World War II U.S. army, founder of the Black Caucus of the American Library Association (BCALA), and a seasoned civil rights activist (Abdullahi, 1992; Poole, 2023), E.J. Josey (1972) argued, “Black librarians are inextricably tied to the problems that affect the larger black community. They have suffered the same hurts, humiliations, discrimination in employment opportunity, lack of promotion on the job, denial of decent housing, and the whole panorama of what it means to be black in a racist society” (p. 5). Community empathy was therefore their stock in trade.

Binnie Tate joined the Los Angeles Public Library (LAPL) staff in 1966 as a children’s service specialist on a federally funded project. After the Watts uprising in 1965, she (1970) found, “White and black communities were trying to find ways to deal with the crisis in our city, which was of course only a reflection of the broader crisis in the nation” (p. 128). Notably, Tate discerned and encouraged her community’s voracious thirst for self-knowledge; this she addressed with Black films, filmstrips, and art programs. Reflecting on her community kinship, Tate concluded, “some of us have made a specific contributions as black librarians” (p. 128). True to their roots, Black librarians, she believed, had a key opportunity—and responsibility—to develop profession-wide social consciousness, i.e. a new form of normative behavior.
THE NEED FOR NEW MODELS OF LIBRARIANSHIP

Although some librarians pushed for outreach to the so-called disadvantaged in the late 19th century and scattered efforts followed thereafter, the post 1940 period represented a new phase (Colson, 1975; Weibel, 1983). The United States’ national social, cultural, and political context demanded a new approach both dynamic and aggressive (Josey, 1966). James Wright (1972) decried rampant “information deprivation” (p. 224) and Ella Yates (1972), incensed at the denial of rights and opportunities to African Americans even after the seismic legislation of the 1960s, insisted that information was linked directly to survival.

Black librarians faced a Sisyphean task in working with urban small worlds and seeking to change community members’ norms concerning institutional mistrust. Reasons for library non-use included “functional or actual illiteracy, distance of residence from existing library outlets, lack of awareness of the library’s location and of the relevance of its materials and services, and low motivations or possible antagonism to the library as a public institution” (National Book Committee, 1967, p. 7). Welbourne (1972a) characterized the library as yet another urban institution “whose purpose and rationale is both meaningless and unknown” (p. 50). In a similarly bleak key, Tate (1970) stated, “Too often, libraries are still ‘castles of knowledge’ protected by a moat of unconcern for the immediate community” (p. 124). Aman (1972), too, skewered the profession’s normative behavior, which offered the Black community “insufficient and inadequate library service; attitudinal barriers which have hampered deliverance of services; and failure to incorporate sufficient numbers of minority groups within the profession” (p. 152). Aman alleged that urban libraries—in parallel with other local institutions—ignored community needs. He found most egregious a general failure to engage people of color in planning or decision-making, thus depriving them of joint ownership. Staring down these challenges, African American librarians readied themselves to work with novel types of information behavior through CBL.

In jettisoning traditional ways and adopting a novel conception of normative behavior, Black CBL involved a push/pull dialectic. Black librarians pushed their services out to the community even as they pulled community members into library buildings and third places as well. Innovative services concentrated on community needs, jettisoning the longstanding metric of circulation statistics (Owens, 1987). Black CBL work therefore augured an important professional shift from materials-centric to user-centric, a shift with longstanding repercussions for the profession. Such work was people- and media- as well as book-centered (Yates, 1972). Adopting this perspective, Wendell Wray (1977) hailed the new community-centered roles of “librarian-politician, librarian-social worker, librarian-educator, librarian-civic leader, and librarian-communicator” (p. 76). These “informational Pied Pipers” represented a shift from passive to active, from the building to the street (p. 84). Wray recommended that librarians cultivate skills in how to conduct forums, clinics, and workshops, hold readings, concerts, lectures, and film festivals, and design exhibits. Such activities would likely attract non-users and ideally, stimulate them to explore other library resources and services. New information behaviors also involved more assiduous service to institutions such as prisons, hospitals, reform schools, and homes for the elderly or handicapped. At the same time, Wray stressed community members’ need for survival information to address information poverty, for example that centering on drugs, abortion, employment, and housing.

Welbourne directed the pathbreaking Urban Information Specialist Program (UISP) at the University of Maryland’s School of Library and Information Services (SLIS) (1970-1); he also worked as SLIS’s first full-time recruiter of students of color. By the 1960s, he (1972b) contended, urban American communities had arrived at a crisis point, struggling to weather systemic daily oppression. “Information is a tool for power and control,” Welbourne explained. “People are kept powerless by what they do not know; they are kept powerless by not having time to fashion alternatives to repressive action” (p. 100). Commissioner of New York City’s Community Development Agency Major Owens (1970) agreed. He believed that timely factual knowledge constituted “weapons in the community arsenal” (p. 1703). To this end, Welbourne (1972a) characterized libraries as a prime testbed for Black community information services.

Following Welbourne and Owens, E.J. Josey (1970b) demanded Black librarians tackle intellectual and social challenges and accommodate nontraditional information behavior. Doing so required taking the library quite literally to the people. Such a “library without walls” Robert Ford (1972) equated to a “university of the streets” (p. 251). This outreach needed to be denuded of any traditionally normative missionary attitude, he insisted; instead it should elevate mutual learning. Thomas Alford (1972) expanded on Ford’s stance: “It is perhaps most important that the public library extend itself beyond its clean, beautifully appointed glass and brick buildings, out into the dirty, littered, ragged, physically and culturally hungry areas of the community. We must get our feet wet and our hands dirty through involvement with the many problems facing the urban poor” (p. 239).

Coordinator of the New Jersey State Library’s Office of Library Service to the Disadvantaged Doreitha Madden also advised librarians to follow the people. Librarians, she enthused (1972), “have taken the library to the people—in community centers, on the streets, in the home, in nursing homes, in prisons—and many are excited by the results” (p. 229). Eleanor F. Brown (1971) encouraged librarians further “to walk [community members’] streets, to make
door-to-door contacts, to attend their meetings, to visit their favorite haunts, to place deposits of books wherever they congregate, to take library materials to them by every conceivable type of mobile equipment” (p. 516).

A pioneer in outreach to the blind, disabled, shut-ins, and underrepresented populations, Ella Gaines Yates, too, advocated immersion. “The only way the librarian can thoroughly understand the workings of a group, its objectives, its needs, and how the library can play a viable role, is to get appointed to offices, committees, and particularly planning committees,” she (1972) maintained (p. 245). In like mind, the Free Library of Philadelphia (FLP)’s John Axam (1970), serving on ALA’s Coordinating Committee on Library Service to the Disadvantaged, urged librarians to engage community information loci—third places in their small worlds—such as barber shops, beauty parlors, laundromats, bars, and churches. In such innovative ways was information poverty fought.

Black community-based librarians turned away from mainstream professional librarianship’s invertebrate focus on the middle-class. Most important, they sought to promote community library services as profoundly useful in ameliorating information poverty. Madden (1972) commented poignantly, “Some librarians learned and responded to the fact that a child can not be interested in a Caldecott Award book if he is hungry—and they fed him” (p. 229). Yates (1972) noticed an increased demand for novel library services; she urged librarians to provide practical information on nutrition, health, and shelter. Accommodating community preferences, Black librarians should cater to users who saw information as “an economic asset, a means of saving money, getting a better job with more pay, and achieving a better standard of living” (Brown, 1971, p. 515).

Not only taking the library to the community but enlisting community residents in the endeavor was a fundamental aim of African American CBL proponents. The National Book Committee (1967) and Brown (1971) advocated training local community members to work in their own neighborhoods and encouraged librarians to enlist community leaders as liaisons. Explicitly foregrounding self-determination, Mohammed Aman (1972) insisted that training local community members to work in their own neighborhoods and encouraged librarians to enlist community leaders as liaisons. Explicitly foregrounding self-determination, Mohammed Aman (1972) insisted that

COLLABORATION WITH OTHER COMMUNITY INSTITUTIONS AND AGENCIES

Another facet of Black community-based librarianship that broke with traditional professional normative behavior was collaboration with other small world community institutions. Despite overlapping responsibilities, rarely did public or private agencies see the library as a potential partner; historically, scant communication, cooperation, and coordination had prevailed (Brown, 1971; National Book Committee, 1967). Black librarians such as Spencer Shaw, Milton Byam, Hardy Franklin, and John Axam sought to change this as they ameliorated information poverty. Their CBL work took place both within and without library buildings; they embraced third places in stirring community

Spencer Shaw (1970) exulted in newfound opportunities “to experiment with innovative approaches in service...as librarians became more socially responsive to ever-expanding publics from different ethnic and economic backgrounds” (pp. 164–165). Shaw’s work in 1940s Hartford, Connecticut, included not only story hours and book talks, but visits to and engagement with a broad swath of local institutions—schools, community centers, and religious institutions. Shaw also explored diverse new venues and drew in new audiences. He held summer story hours in city parks, lectured at local colleges, offered in-service courses for teachers, and penned book reviews for the Hartford Courant.

After joining the Brooklyn Public Library (BPL) in 1948, Shaw further extended his community-based work. He made daily elementary and junior high school visits as well as some high school visits, including to public, private, and parochial schools and yeshivas. Shaw used branch libraries for class visits and story hours; he also held summer story hours in local parks and stationed a Library-on-Wheels at nearby housing projects. Shaw gave talks to members of parent-teacher associations, to senior citizens groups, and to civic and social groups. He dived into media beyond books, too, namely recordings and radio. In the latter case, he spoke on behalf of the National Association for the Advancement of Colored People (NAACP), Negro History Week, the local Council of Churches, and various public service programs. Shaw found CBL’s payoff immense. “I had touching moments with the handicapped, disturbed or delinquent children I met in special schools, institutions or hospitals,” he (1970) recalled. “One could not remain insensitive to the true worth of library service” (pp. 160–161).

A BPL stalwart like Shaw, Milton Byam (1970) also flourished as a result of a literary upbringing. “I feel as if I were intended to be a librarian from the beginning,” he wrote, recalling a childhood of “unappeased hunger for books” (p. 50). Intellectual curiosity aside, Byam attributed his commitment to community-based librarianship to his World War II service in the segregated U.S. Army. This experience, he noted, “tore me away from notions of scientific perfectibility to concern for people...How could I design airplanes while blacks lived in the abject poverty of the Louisiana swamplands?” (p. 50). Byam determined to embark upon a career helping people.
Stationed at Bedford Youth Library in 1949, Byam ignited the branch’s community commitments. “With enthusiasm, we went to work with the youngsters, permitting them to rehearse a play in the library auditorium, teaching them to use a printing press, and even giving a dance and show at the Carlton Avenue ‘Y,’” he (1970) wrote (p. 55). Users warmed especially to the branch’s jazz and popular record collection; they also found the library a repository of useful occupational and career information. Building on this work, a year later Byam joined Brooklyn’s bustling New Utrecht Branch, a storefront that served a diverse local population. Byam plunged once more into community work. Although he started book discussion groups, perhaps more important were his efforts outside the library, which included local high school talks and Community Council meetings. Like Shaw, Byam ascribed great rewards to his CBL work. “Groups thought of the library first in planning programs and meetings,” he (1970) remembered. “Stores gave regular discounts to all library staff members. I and my staff were invited to speak at all types of community gatherings from Chambers of Commerce and P.T.A.’s to housewives’ discussion groups” (p. 59).

Still another CBL mainstay, Hardy Franklin served as a U.S. Army librarian in Okinawa between 1953 and 1955 before beginning work at BPL in 1961 as Community Coordinator. He soon became “a designated ‘missionary’ for the system” and consequently “‘Mr. BPL’ to hundreds of children, young adults, and adults” (Smith, 1965, p. 225). Not merely a field agent, Franklin attended local organizations’ meetings and spoke with “dozens of parent-teacher groups, church organizations, political clubs, and block improvement associations”; he also served as an officer or board member for many of them (Smith, 1965, pp. 225–226). Franklin’s success spurred BPL to appoint three more Community Coordinators. “Freed from desk schedules,” these coordinators “work[ed] actively with the various government financed projects, such as those for youth, adult basic education, manpower training, and programs of aid for dependent children” (Smith, 1965, p. 226). Such coordinators took on numerous roles: “neighbor, counselor, social worker, and teacher as well as librarian” (Black, 1970, p. 44). Once more, CBL reckoned with small world information poverty, seeking to provide communities with pleasurable as well as practical information. Such work’s payoff was substantial, even if partnerships remained difficult to cultivate, much less to sustain.

**EXEMPLARY BLACK CBL INITIATIVES**

Programs at the Free Library of Philadelphia and the San Francisco Public Library represented watershed CBL initiatives that hinted at the ability of Black librarians to fight information poverty and to change normative behaviors that militated against library use. These African American librarians followed the people, they broadened the scope of traditional library services, they promoted varied media, they collaborated with other community social agencies, and they earned community buy-in and joint ownership.

A first example of model CBL took place at FLP. In 1964, John Axam acceded to the Head of the Free Library of Philadelphia’s Stations Department, which constituted “a library without walls” (Milner, 1976, p. 14). The Stations Department deposited books and offered programs to hospitals, recreation centers, housing projects, private homes, prisons, shut-ins, and community centers; it also operated three bookmobiles.

In the late 1960s, Axam’s FLP followed other Philadelphia agencies and tackled social problems (Axam, 1987). Through initiatives such as the Reader Development Program (RDP) (1967-1969), the library’s approach evolved from a focus on service to the middle-class to a more inclusive one. Key to this was facilitating basic adult education, especially that of “functionally illiterate” Philadelphians. RDP staff visited local social agencies not only to promote RDP services and gather information on each agency’s needs, but also to encourage agencies’ staff members to review and provide input and feedback on RDP’s demonstration materials.

One new Stations Department initiative, the Home Collections project, germinated in a conversation between a community health worker and a librarian (Axam, 1987). Six neighborhood mothers thereafter administered small paperback collections out of their homes. A block party kickoff event included a modern dance group, a dance band, and community member-prepared cake and punch. Stations Department personnel subsequently made consultation visits and changed out books.

Axam also led the establishment of two Teen Centers. The Wilson Park Teen Center boasted both recreational and educational activities. Notably, the center employed local teens. St. Andrews Teen Drop-In Center also brought in “eager and very conscientious teenage volunteers [who] were trained to charge out, check in, and otherwise oversee the collection” (Axam, 1987, p. 138). The Center featured a paperback book rack to draw teen interest and offered classes in babysitting, sewing, arts and crafts, cooking, and even folk singing.

In a final BL initiative, FLP adapted a familiar institution to community circumstances. When a parent requested a bookmobile, which was not logistically feasible, the Stations Department instead stocked a station wagon. It circulated weekly during the summer of 1968, carrying between 150 and 200 books for children and teenagers as well as books requested by their parents. Staff displayed books on a table provided by the neighborhood mothers and on the vehicle’s tailgate. Mothers also hosted story hours in their living rooms. In the summer of 1969, the program expanded to include living room film showings as well as story hours. Complementing this work, a Summer Bookmobile Program ported local cultural institutions’ exhibits and displays into communities.
A second exemplary CBL initiative was San Francisco Public Library’s Fillmore Street Reference Project, which came to life in the summer of 1968 under the inspiration of Black librarian Olive Wong. Rejecting librarianship's normative focus on information confined to library buildings, the project sought to hook community members on information relevant the rhythms of their small worlds. Wong pitched “a rather remarkable idea: to circulate books without a card, and to work out of an official city car on a litter-cluttered corner in the heart of the ghetto. We would simply ask people if there were any book or information we could get for them and come back the next day with the desired material” (Bennette, 1969, p. 872).

Choosing staff well-suited for community work was essential. Notably, not one of the staff was a professionally trained librarian. Instead, they were “selected primarily for ability to relate; to talk to people, to listen to and accept without judgment the mores, rhythm, and cultural assumptions of the street population” (Bennette, 1969, p. 875). To stir interest, project staff organized Black history discussion groups for local youths at a branch library. They also attended meetings of the Youth for Service, Young Men for Action, Economic Opportunity Center, Human Rights Commission, and Western Addition Youth to obtain buy-in.

Three afternoons a week, the car visited one of three designated street corners, displayed a box of diverse books, and let community members’ curiosity percolate. “We are structuring ourselves to be included and not injected into the mainstream of the community,” Bennette (1969) maintained (p. 875). Alas, both programs proved short-lived.

**PAYOFFS AND COSTS**

Black community-based librarianship yielded extraordinary rewards—but also incurred substantial costs. Reflecting on his longstanding Freedom Struggle advocacy, Josey (1970) wrote, “I became a better librarian…by being part and parcel of the swiftly moving social currents that were going on around me in the community”; this gave him “a more informed, disciplined and stringent understanding of what libraries could do for people” (p. 323). At Savannah State University, Josey strongly supported local sit-ins in 1960, serving as faculty advisor to the students involved and working closely with the Savannah branch of the National Association for the Advancement of Colored People (NAACP). As an extension of this work, Josey stumped successfully for desegregation of the Savannah Public Library Board and was one of the first two African American members of that body (1962) (Josey, 1970a). Unlike Josey, Vivian Hewitt had to tamp down her community-based activism for fear of some white library administrators’ disapproval. “When I participated in a number of restaurant sit-ins, I kept this fact concealed from the library lest my activities ‘reflect’ on it,” she (1970) recalled (p. 261). Even so, she characterized her Wylie Branch years as “inspiring, educational, and exhausting” (p. 261).

Like Josey and Hewitt, other Black CBL pioneers appreciated their small world CBL work, though they also stressed its costs. Baker (1970) reflected, “My community work was often exhausting but it was so very rewarding” (p. 119). Highlighting the “almost unquenchable thirst for knowledge of self among Afro-Americans and other minorities,” Tate (1970) wrote, “I shall always be thankful, in spite of the many frustrations, for the opportunity to contribute” (p. 128). Ford (1972) found CBL “a complex and emotionally-draining experience” but maintained that the “rewards in terms of personal satisfaction are immense and well worth waiting for” (p. 252). Yates (1972) expressed a still more ambivalent view, calling her CBL efforts “highly demanding, exhausting, and often very frustrating” (p. 245).

Some Black librarians faced obstacles to their CBL work. Yates (1972) pointed to a troubling gap between rhetoric and action in addressing marginalized communities’ information needs, a point reprinted by Tate (1972). Despite their professed commitment, senior administrators rarely participated in this work. Yates (1972) feared this stigmatization, for it discouraged “many young, dynamic, inventive [B]lack librarians” from community engagement, especially given low salaries and chances for professional advancement (p. 244). Exacerbating matters, CBL demanded time-consuming and laborious immersion to understand communities’ often nontraditional information behavior.

Despite his CBL achievements, Milton Byam also encountered obstacles. In 1955, he was transferred to Williamsburg, Brooklyn. Urban renewal had demolished most houses and buildings near the library and had uprooted the community. Those who remained included Blacks, Hasidic Jews, Lithuanians, Poles, Latvians, Finns, and Italians. The experience seemed an ideal laboratory to test community-based librarianship, but Byam met frustration. He (1970) remembered, “The chief problem was that it was not ever a community but a conglomerate of communities, and one had to run all over the map to service it” (p. 61).

Another example of CBL failure cropped up in LIS education. Responding to LIS programs’ apparent indifference toward and irrelevance to real world problems and to non-white and non-middle class constituents, in the fall of 1970 the University of Maryland launched an Urban Information Specialist Program (UISP), with Welbourne, Jr., as its director (Bundy, 1987). Animated by Blacks’ battle for social justice and avowedly anti-racist, UISP supported Blacks’ securing of self-determination, including separatism (Bundy, 1971).

The program pivoted around “service to the people” broadly construed (Welbourne, Jr., 1972b, p. 100). It focused on the ecumenical use of information resources, including multimedia, in urban communities, not just on libraries
and books. UISP also foregrounded field experiences and evolving information needs in light of technological change (Bundy, 1971).

Recruited students were “people who had never been to college before, people who had only lived in the ghetto and waited for the chance for some institution to open up and say, ‘You can use your mind to think and solve problems; the sky is the limit’” (Welbourne, Jr., 1972b, p. 104). UISP thus inaugurated a new work role: an information interpreter and advocate who liaised between community members, social agencies including libraries, and needed information resources (Bundy, 1971).

But the program lasted only a year, proving unable to secure further funding from federal agencies or the university. Racism seemed “an active, vital and institutionalized social force” in the program’s truncation; Bundy and Welbourne (1974) castigated the university’s “unsympathetic and hostile control groups” (pp. 1, 2). Suffice it to say that the gains of Black CBL remained fragile indeed.

**CONCLUSION**

As part of a massive conservative political, social, and cultural counterrevolution, Presidents Richard Nixon and Gerald Ford hollowed out federal funding to libraries in the mid-1970s (Carter, 1996; Holley & Schremser, 1983). This ebbing of funds, unstable and short-term as they already were, had a pernicious effect on many CBL programs. Urban libraries were often unable to save these programs without federal support, and traditional reliance upon circulation statistics as justification for funding reemerged (Weibel, 1983; Wiegand, 2015). Meanwhile, many pathbreaking Black librarians moved away from community work into administration or moved to different institutions altogether, also hindering CBL’s staying power. Finally, novel library and information science education initiatives that prepared students of color for the profession or that trained students to do community-based work faltered (Bundy, 1987). Information poverty as lived in small worlds was profoundly difficult to vanquish. As hard as they worked, Black librarians committed to CBL encountered mixed success in doing so.

This previously untold history makes six scholarly contributions. First, it highlights the African American middle class’s often overlooked and even slighted role in the Freedom Struggle. African American librarians served as often hidden but nonetheless effective civil rights avatars. Second, although scholars emphasize the vital role of Black women’s inveterate community engagement and uplift, this paper shows that African American men, too, made crucial contributions. Third, our work narrates Black librarians’ efforts to combat information poverty through a specifically Black community-based librarianship. In doing so, this research illuminates the roots of 21st century community-based librarianship and elevates Black librarians to pride of place in the CBL discourse. Fourth, the history of Black CBL reminds us that access to quality, trusted information is a human right. Fifth, this paper suggests the benefits of expanding Chatman’s notion of information poverty to include not only the informative, but also the ludic and edifying aspects of information, including storytelling, heritage, and history. We suggest that an expanded, more holistic conception of information poverty permits an even more fruitful exploration of information behavior, small worlds, and normative behavior. Sixth and finally, our work underlines the relevance of Chatman’s scholarship for historical research.

Not only does historical Black CBL work contribute to the scholarly literature, but it has numerous implications for current practice, since information poverty remains very much with us. We recommend that information professionals immerse themselves in their local communities; reappreciate and attend to the importance of place, including third places whether physical or virtual; ally with and participate as members in other social agencies; embrace new technology and new multimedia; and recruit and retain more librarians who live in the communities in which they work and who have similar lived experience to those they serve. Further, as information scientists Bharat Mehra and Ramesh Srinivasan (2007) assert, we must avoid perpetuating historical patterns in which we slight or ignore our local community partners, whether urban or rural, thereby not only forestalling salutary learning and cultural exchange, but undercutting our own relevance.

We propose three questions for future research. First, how did international CBL efforts resemble or differ from those in the United States? In western Europe in the 1960s and 1970s, for instance, Martin (1975) saw librarianship assuming an augmented social role, taking up arms against poverty and inequity in league with other social institutions. How common were such initiatives and what were their outcomes? Second, although we focus here on Black librarians in the United States, how did librarians of other races, ethnicities, and socioeconomic classes engage their communities? Third, given the paucity of meaningful data offered by circulation statistics, as these pioneers contended, how might we most effectively advocate for resources to support current CBL activities and initiatives?

Chatman (1996) insists that information professionals bear “an obligation to continue to work to identify issues that examine the information needs of...populations that have traditionally been overlooked by our research efforts, professional practice, and the published literature” (p. 205). We hope this paper encourages current information professionals to take a step in this direction; as historian Carl Becker (1932) contends, “The history that lies inert in
unread books does no work in the world” (p. 234). Research, that is, must be translated into practice. Black community-based librarians constructed a roadmap for doing so.

Study on the Characteristics of Cross-Domain Knowledge Diffusion from Science to Policy: Evidence from Overton Data

Ren, Chao  School of Information Resource Management, Renmin University of China | renchao@ruc.edu.cn
Yang, Menghui  School of Information Resource Management, Renmin University of China; Key Laboratory of Data Engineering and Knowledge Engineering, Ministry of Education, China | yangmenghui@ruc.edu.cn

ABSTRACT
The cross-domain knowledge diffusion from science to policy is a prevalent phenomenon that demands academic attention. To investigate the characteristics of cross-domain knowledge diffusion from science to policy, this study suggests using the citation of policies to scientific articles as a basis for quantifying the diffusion strength, breadth, and speed. The study reveals that the strength and breadth of cross-domain knowledge diffusion from scientific papers to policies conform to a power-law distribution, while the speed follows a logarithmic normal distribution. Moreover, the papers with the highest diffusion strength, breadth, and fastest diffusion speed are predominantly from world-renowned universities, scholars, and top journals. The papers with the highest diffusion strength and breadth are mostly from social sciences, especially economics, those with the fastest diffusion speed are mainly from medical and life sciences, followed by social sciences. The findings indicate that cross-domain knowledge diffusion from science to policy follows the Matthew effect, whereby individuals or institutions with high academic achievements are more likely to achieve successful cross-domain knowledge diffusion. Furthermore, papers in the field of economics tend to have the higher cross-domain knowledge diffusion strength and breadth, while those in medical and life sciences have the faster cross-domain knowledge diffusion speed.

KEYWORDS
Science and policy; cross-domain knowledge diffusion; diffusion strength, breadth and speed; Overton.

INTRODUCTION
In recent years, the phenomenon of cross-domain knowledge diffusion from science to policy has become increasingly evident (Nay & Barré-Sinoussi, 2022). This refers to the process of introducing scientific research findings into policy development and implementation to address specific problems and challenges (Hodges et al., 2022). In this process, scientific research results need to be transformed into specific policies and practical measures to meet the needs of policy makers and implementers (Watson, 2005). According to Overton data, in 2021, over 660,000 policy documents were published worldwide, of which 44,875 policies cited 468,194 scientific articles (Szomszor & Adie, 2022). This indicates that policy makers are increasingly relying on scientific research findings to formulate policies. This phenomenon can be understood as a manifestation of the scientific and refined nature of policy making and highlights the universality and importance of cross-domain knowledge diffusion from science to policy.

While cross-domain knowledge diffusion of science to policy has become a global trend and has had significant impacts on social and economic development, there is still insufficient attention given to this phenomenon in the academic community, particularly in the field of quantitative research. This may be due to various factors such as a lack of research data, time lags between policy and science, and differences in research methods between policy-making and scientific research (S. O. Funtowicz & Ravetz, 1990). However, this fact cannot conceal the truth that we still lack the ability to accurately grasp the underlying characteristics of cross-domain knowledge diffusion of science to policy. A precise comprehension of the cross-domain knowledge diffusion characteristics of science to policy is of significant importance in promoting an effective linkage between science and policy, enhancing the scientific validity and feasibility of policies, driving scientific development and innovation, and optimizing the allocation of policy and scientific resources (Pielke, 2007).

Therefore, using Overton's data as a basis, this paper aims to address the following questions related to this phenomenon: (1) How can we explore the characteristics of cross-domain knowledge diffusion of science to policy from massive data? (2) What are the current characteristics of cross-domain knowledge diffusion of science to policy? To tackle those questions, this paper collected policy data and the scientific papers cited by them. Based on the citation relationships between policies and papers, a citation network was constructed. Diffusion strength, diffusion breadth, and diffusion speed were proposed as indicators to measure the characteristics of cross-domain knowledge diffusion of science to policy. The structure of this paper includes an introduction in Section 1, related work in Section 2, Section 3 introduced the data and methods, presentation and discussion of the results of the cross-domain knowledge diffusion of science to policy was conducted in Section 4, and a conclusion in Section 5.
RELATED WORK

The investigation of the relationship between policy and science has a long history (Boswell & Smith, 2017). In previous research, S. Funtowicz (2006) distinguished several conceptual models of the relationship between science and policy decision-making, including the modern model, the precautionary model, the frame model, the boundary model, and the extended participation model. Those studies are significant in understanding the relationship between policy and science. However, some scholars argue that policy and science are highly unrelated fields. For instance, the two-community theory highlights the substantial gap between scientists and policy-makers and separates science research from the policy process (Caplan, 1979).

But in the current era, especially since the outbreak of the COVID-19 pandemic, the relationship between policy and science has become increasingly close (Yin et al., 2021). Taking the development of COVID-19 policies as an example, on the one hand, COVID-19 policies can influence the direction of science (Gao et al., 2021). The stay-at-home orders and remote work caused by the pandemic have led to a significant decrease in efficiency and output for most scientists, which could have important impacts on their careers. At the same time, life sciences, clinical sciences, and some basic sciences will have the best development prospects after the pandemic, while disciplines that require field research and frequent work-related travel will continue to be affected (Myers et al., 2020). This will have a profound impact on the historical process of scientific research. On the other hand, scientific research provides scientific advice and guidance for the formulation of COVID-19 policies, and governments around the world hope to develop the most reasonable policies based on scientific evidence (Moatti, 2020). Research has found that the popular topics in Chinese scientific research during the early stages of the pandemic were extremely similar to related policies, with scientific research results being transformed into COVID-19 policies an average of 8.36 days after publication (Cheng et al., 2021). Similarly, Yin et al. (2021) accurately understood the co-evolutionary relationship between scientific research and policy during the COVID-19 pandemic by tracking the citation relationship between policy and science.

The exploration of the relationship between policy and science has important implications for our understanding of the cross-domain knowledge diffusion of science to policy. In particular, quantitative research on the relationship between policy and science is crucial for characterizing this phenomenon. As demonstrated in previous research (Yin et al., 2021), the use of policy documents citing scientific papers can help to explore the co-evolution of policy and science. This citation relationship can also be used to describe the cross-domain knowledge diffusion of science to policy. Policy documents citing scientific papers means that the viewpoints expressed in the scientific papers are spreading to the policy documents. The citation network of policy documents to scientific papers can be expanded to a cross-domain diffusion network of scientific papers to policy documents. To characterize this network, this paper draws on previous studies that analyze diffusion characteristics based on citations in bibliometrics.

Research on diffusion characteristics based on citations is derived from the study of knowledge diffusion in bibliometrics. British scholar Rowlands proposed the concept of "journal impact factor", which measures the diffusion of knowledge by treating journals as knowledge units (Rowlands, 2002). This innovation introduces a new citation parameter related to the concept of diffusion. Subsequently, informatics scientists such as Fairthorne and R. Rousseau conducted further research (Fairthorne, 1969), proposing relevant quantitative indicators and calculation methods such as diffusion strength, diffusion breadth, and diffusion speed (Rousseau, 2005). These metrics are used to analyze the characteristics, trends, and connections of knowledge dissemination and communication processes, expanding the scope of analysis from journals to disciplines, patents, and other types of documents (Ding et al., 2021).

In addition, quantitative research on the cross-domain knowledge diffusion of science to policy requires extensive data support. We know that the Overton database includes a large amount of policy data from various countries, from which policy documents and scientific papers cited by these policies are extracted, providing a data foundation for us to explore the characteristics of cross-domain diffusion from science to policy (Szomszor & Adie, 2022). Therefore, based on the Overton data and drawing on relevant research on knowledge diffusion characteristics, this paper conducted a quantitative analysis of the characteristics of cross-domain diffusion from science to policy from three aspects: diffusion strength, diffusion breadth, and diffusion speed.

DATA AND METHODS

Data

This article draws on policy document data from the Overton database, which is currently the largest policy database in the world, providing over 1,000 different sources of policy documents from different countries around the globe (however, relevant policy data from mainland China is not included due to data acquisition issues). The study retrieves all the metadata of policies published globally throughout the year 2021 from the Overton database, totaling 588,786 entries. Each record includes information such as policy release time, title, full-text PDF link, policy release type, policy classification, keywords, and citation relationships (Szomszor & Adie, 2022). Among
them, keywords are the main themes of a document. Overton analyze the phrases and entities used in the document and then compare them to data derived from pages on Wikipedia to find which ones have the most in common. In addition, Overton look for discipline areas the same way they do topics, but documents are matched against examples from each category in the IPTC’s Media Topics controlled vocabulary instead of against Wikipedia pages. Media Topics are the categories used by many newspapers and magazines to organize their articles (Szomszor & Adie, 2022). According to the author’s expertise, the Overton Database is currently hailed as the most comprehensive and sophisticated global database, seamlessly integrating policy and science. The entities extracted by this database have attained an exceptional level of accuracy, setting a benchmark in the field. When it comes to policy classification and topic extraction, the Overton Database stands out as one of the most precise and reliable databases worldwide, leaving a remarkable impact in the realm of policy databases (Szomszor & Adie, 2022).

Among the 588,786 policy documents analyzed, a total of 1,164 government, international organizations, and think tank entities from 211 countries and regions were identified. Out of these documents, 44,875 referenced scientific papers, resulting in 468,194 unique scientific papers cited by policies. To study the cross-domain knowledge diffusion from science to policy, we extracted the DOI numbers of the cited scientific papers from these 44,875 policy documents and retrieved the corresponding metadata from the OpenAlex database, which is a large and free academic resource index containing over 200 million scientific publications. The metadata for the scientific papers includes information such as the title, publication date, journal, author details, citation count, references, keywords, and subject. The keywords and discipline were obtained from the Microsoft Knowledge Graph, who was inherited by OpenAlex (Priem et al., 2022). Therefore, this study explores the characteristics of cross-domain knowledge diffusion from science to policy based on the analysis of 419,936 scientific papers cited by the 44,875 policy documents. The OpenAlex database draws the majority of its data from the highly comprehensive Microsoft Knowledge Graph (MAG). With its extensive data coverage, MAG serves as an invaluable source. For instance, we were able to extract 468,194 paper DOIs from policy data, subsequently retrieving 419,936 papers within the OpenAlex database. Remarkably, both OpenAlex and MAG databases exhibit outstanding accuracy in critical tasks such as author name disambiguation, publication categorization, and embeddings. These exceptionally precise outcomes form a solid foundation to support the research presented in this paper, underscoring the reliability and significance of the findings (Färber & Ao, 2022).

**Methods**

In this paper, we adopt diffusion strength, diffusion breadth, and diffusion speed, which are commonly used in the analysis characteristics of knowledge diffusion, to investigate the characteristics of cross-domain knowledge diffusion from science to policy (Rousseau, 2005). The specific indicators and measurement methods are shown in Table 1.

**Table 1. The diffusion indicators and measurement methods**

Diffusion strength refers to the counts a scientific paper is cited by policy documents. The more counts it is cited, the greater its impact on policy, including absolute and relative strength. Absolute strength is used for analyzing and comparing data within the same set, while relative strength is used for analyzing and comparing data from different
sets. For example, if paper A is cited by m policy documents and there are n citation relationships in the dataset, the absolute diffusion strength of paper A is m, and the relative diffusion strength is m/n.

Diffusion breadth refers to the number of policy institutions that cite a scientific paper, representing the coverage of the paper. The more institutions that cite the paper, the greater its coverage. This includes both absolute breadth and relative breadth, which are comparable to diffusion strength. For instance, if paper A is cited by l different policy-making departments and the dataset of policy citations contains s policy-making departments in total, then the absolute diffusion breadth of paper A is l, and the relative diffusion breadth is l/s.

Diffusion speed refers to the rate at which a scientific paper is cited by policy documents. The shorter the time between publication and citation, the faster the speed. This includes both diffusion strength and diffusion breadth, which respectively measure the speed of the paper's spread to policy institutions and the spread to policy-making organizations. For example, if paper A is cited by policy B, and the publication date of paper A is January 2nd, 2021, while policy B's publication date is January 28th, 2021, the citation interval for paper A is 28 days. The strength diffusion speed is m/28, and the breadth diffusion speed is l/28.

In the calculation process, a scientific paper may be cited by multiple policy, so there may be multiple values for the diffusion spread days (SD) of a paper. We take the average of these values as the SD of the paper. For example, if paper A has three citation pairs (paper A, policy B), (paper A, policy C), and (paper A, policy D), with corresponding citation intervals of 10 days, 30 days, and 50 days, then the SD of paper A is ((10 + 30 + 50))/3 = 30. Using this calculation method, this study obtained nine indicators, including absolute and relative strength, absolute and relative breadth, diffusion spread days, absolute and relative strength diffusion speed, and absolute and relative breadth diffusion speed, for 419,936 scientific papers, in order to explore the cross-domain characteristics of scientific papers towards policies.

RESULTS AND ANALYSIS
After obtaining 419,936 indicators of cross-domain diffusion strength, diffusion breadth, and diffusion speed of scientific papers, this study presents and analyzes the results in three parts: data distribution of diffusion characteristics, analysis of diffusion strength and breadth, and analysis of diffusion speed. In the data distribution part, we investigate the distribution patterns of the indicators and the correlations among them. In the other parts, we explore the attribute and content characteristics of the top 1% scientific papers with the highest diffusion strength and breadth, as well as the fastest diffusion speed. Attribute characteristics refer to information such as the authors, institutions, and journals of the papers, while content characteristics refer to the discipline classification and keywords of the papers.

Data distribution of diffusion characteristics
We first examined the data descriptions and distributions of the nine indicators of cross-domain diffusion in 419,936 scientific papers, including AS, RS, AB, RB, SD, SAS, SRS, SAB, SRB in Table 1. The results of the data descriptions are shown in Table 2 and distribution analysis is in Figure 1. Table 2 shows the data descriptions of the nine indicators, including the count, mean, standard deviation, minimum, maximum and quartiles of each indicator.

Table 2. The data descriptions of diffusion characteristics

The first four graphs in Figure 1 show the distribution of the four indicators of AS, RS, AB, RB in a log-log coordinate system, indicating that the data distribution almost follows a straight line, which means the data of AS, RS, AB, RB in cross-domain knowledge diffusion of scientific papers follow a power-law distribution. The remaining five graphs in Figure 1 show the distribution of the five indicators of SD, SAS, SRS, SAB, SRB in a log-linear coordinate system, indicating that the data distribution almost follows an approximately normal distribution, which means that the data of SD, SAS, SRS, SAB, SRB in cross-domain diffusion of scientific papers follow a log-normal distribution. We also tested the data distributions using the Kolmogorov-Smirnov test and found that AS,
RS, AB, RB fit the power-law distribution and SD, SAS, SRS, SAB, SRB fit the log-normal distribution. The power law distribution of the strengths and breadths of cross-domain knowledge diffusion suggests that a select few highly cited papers have a substantial influence on policy. This phenomenon, known as the Matthew effect (Merton, 1968), implies that certain papers may be more frequently cited by policies, resulting in a greater impact on policies (Wang, 2014). Moreover, the logarithmic normal distribution of the speed in cross-domain knowledge diffusion indicates that there is variability in the speed at which papers spread, with some papers spreading more quickly than others. Additionally, the long tails of logarithmic normal distributions suggest the existence of a few extremely fast-spreading papers, which may significantly contribute to the diffusion process. Conversely, the majority of papers spread at a slower pace. The presence of both power law and logarithmic normal distributions highlights the nonlinear and non-uniform nature of cross-domain knowledge diffusion of science to policy, and the potential existence of a Matthew effect stemming from a small number of extreme or high-end values.

The intensity, breadth, and speed of cross-domain diffusion of scientific papers to policy exhibit a pronounced Matthew effect, wherein a small number of papers are extensively and widely cited in policy domains. Simultaneously, these select few papers experience a rapid and widespread diffusion to policy circles, while the majority of papers have a slower rate of diffusion. This Matthew effect refers to the phenomenon in which a small subset of highly influential or widely cited papers attracts greater attention and citations, thus further amplifying their impact and citation count (Merton, 1988). Several factors contribute to this phenomenon: those few scientific papers that prominently permeate across domains into policy circles often make significant contributions to problem-solving, theoretical development, or empirical analysis, and they may address issues of substantial social impact. The authors of these papers may be renowned experts in their fields or possess a distinguished academic reputation. Moreover, these papers enjoy enhanced visibility and benefit from wider dissemination channels in both academic and policy spheres, being published in high-impact journals, receiving media coverage, or being recognized as noteworthy research achievements.

Figure 1. the distribution patterns of the diffusion indicators
Due to the non-normal distribution of the nine diffusion indicators, this study utilized the Spearman correlation coefficient to measure the correlation among the indicators. The results are shown in the correlation matrix in Figure 2. The absolute and relative indicators of diffusion were found to be highly correlated, with a correlation coefficient of 1. This indicates that they exhibit the highest positive similarity when changing, as determined by the relative indicator calculation method. The correlation coefficient between diffusion strength and diffusion breadth was 0.76, indicating that they are highly positively correlated. This suggests that the changes in the strength and breadth of scientific papers' cross-domain knowledge diffusion to policy are consistent. Specifically, the number of times a paper is cited in a policy and the coverage of the paper in policy institutions are highly positively correlated. The correlation coefficient between SD and SAS, SRS, SAB, SRB is below -0.93, indicating that they are highly negatively correlated. This negative correlation is also determined by the calculation method of SAS, SRS, SAB, SRB. It is worth noting that although SAS, SRS, SAB, SRB are calculated as ratios of AS, RS, AB, RB and SD, their magnitude is mainly determined by SD, rather than AS, RS, AB, RB. The correlation coefficient between AS, RS and AB, RB is 0.97, indicating that they are highly positively correlated. This means that the speed of scientific papers' cross-domain diffusion to policies and the speed of scientific papers' diffusion to policy institutions are highly positively correlated. The correlation coefficients between the other indicators are relatively low. This is especially true for the correlation coefficient between SD and AS, RS, AB, RB, which is close to 0.09. This indicates that there is almost no linear relationship between the diffusion strength and breadth of scientific papers' cross-domain diffusion to policies and the diffusion spend days in which the paper is cited in policies.

### Analysis of diffusion strength and breadth

Due to the high positive correlation between diffusion strength and breadth, this study also found that the characteristics of papers with high diffusion strength and those with high diffusion breadth are extremely similar. Therefore, we analyzed diffusion strength and breadth together.

In this section, we investigate the attribute and content features of the top 1% most highly diffused scientific papers in terms of diffusion strength and breadth. The attribute features are presented in Table 3 and include the top ten countries, institutions, authors, and journals with the highest frequency of publications in both absolute diffusion strength and breadth. For example, "USA (1517)" indicates that 1517 papers in the top 1% scientific papers of highest absolute diffusion strength and breadth are from the USA. From Table 3, we observe that the majority of scientific papers of highest absolute diffusion strength and breadth are from Western countries, with the USA having the largest number of papers. This may be due to Overton's focus on Western countries' policies, making papers from these countries more likely to be cited by local and neighboring countries. Regarding institutions, the scientific papers of highest absolute diffusion strength and breadth are mainly from world-renowned universities, especially those in the USA, such as Harvard University and MIT. There are also international organizations, such as Organization for Economic Co-Operation and Development. Concerning authors, the majority of highly diffused scientific papers are authored by outstanding scholars who come from world-renowned universities, whom are primarily distinguished scientists in economics and environmental sciences, but also some
are experts in law and public health. Concerning journals, scientific papers of highest absolute diffusion strength and breadth are from top-tier social science research journals in economics and social development worldwide. Additionally, some papers are from medical journals, such as The Lancet, and comprehensive journals, such as Science, Nature and Proceedings of the National Academy of Sciences of the United States of America.

**Table 3. Attribute Features of the Papers with the Highest Diffusion Strength and Breadth**

The content characteristics of a paper include the discipline classification to which it belongs and the keywords that represent its main themes. In this study, we used data provided by OpenAlex to create pie charts depicting the proportion of discipline classifications for papers with the highest diffusion strength and diffusion breadth, as well as word clouds for their main keywords, as shown in Figure 3.
Figure 3. Content characteristics of papers with the highest diffusion strength and diffusion breadth.

Figure 3(a) and (b) respectively show the proportion of disciplines of papers with the highest diffusion strength and the word cloud of the main themes of these papers; Figure 3 (c) and (d) respectively show the proportion of disciplines of papers with the diffusion breadth and the word cloud of the main themes of these papers. From Figures 3(a) and 3(c), it can be seen that the discipline classification with the highest proportion for papers with the highest diffusion strength and diffusion breadth is economics, which is much higher than other classifications. The next most common classifications are business, medicine, and environmental science, with social sciences being the most prevalent. Natural sciences have a very low proportion, and medicine and life sciences, which are mainly focused on COVID-19, have a slightly higher proportion. From Figures 3(b) and 3(d), it can be seen that the main themes of papers with the highest diffusion strength and diffusion breadth focus on four main areas: public health issues (COVID-19, public health, healthcare), climate issues (climate change), employment issues (wage, unemployment), and social development issues (developing country, population, inequality). These issues were the main focus of policy-making in various countries worldwide in 2021, especially with the global pandemic of COVID-19 having far-reaching impacts on the economy, society, and environment of countries around the world. Therefore, many countries had to formulate policies to address these issues, and scientific papers on these topics have greatly contributed to policy diffusion.

Analysis of diffusion speed

We also investigated the attribute and content characteristics of the top 1% of scientific papers with the smallest diffusion spend days, the fastest diffusion speed of strength and breadth. The attribute information is shown in Table 4, and the content information is shown in Figure 4.
Table 4. Attribute features of the fastest spreading scientific papers

From Table 4, it can be seen that the majority of the top 1% of scientific papers with the fastest diffusion speed are almost from Western countries, with the USA having the highest number. Regarding institutions, the fastest spreading scientific papers mainly come from well-known universities in the USA, UK and National Institutes of Health. However, Johns Hopkins University were not included in Table 3, although their medical specialties are excellent. Combined with the National Institutes of Health being included, we speculate that the fast spreading of COVID-19-related papers in policies may have caused this. In terms of journals, papers with the fastest diffusion speed were mainly published in open access journals, including some preprints in the biomedical field (medRxiv), medical journals (BMJ, The Lancet, Eastern Mediterranean Health Journal and The New England Journal of Medicine), some social science journals (Social Science Research Network). This may be due to the impact of COVID-19, with papers related to COVID-19 spreading rapidly in policy circles.
The discipline classifications and word cloud of the top 1% of papers with the fastest spread are depicted in Figure 4. Figure 4(a) shows that medicine has the largest proportion in the top 1%, followed by political science and business. Overall, medicine and life sciences have the largest proportion, followed by social sciences, which differs significantly from the discipline classifications of papers with the highest diffusion strength and breadth shown in Figure 3. Figure 4(b) illustrates that the main themes of the fastest spreading papers focus on two aspects: public health issues (such as public health, epidemiology, vaccination, and virus) and social development issues (such as population). Among them, papers related to COVID-19 public health issues have the largest number, indicating that interdisciplinary papers on public health issues related to COVID-19 spread to policy at the fastest speed. This finding further confirms that COVID-19 has had a significant impact on the speed of papers spreading to policy in 2021, and papers focused on public health issues (in medicine and life sciences) tend to have a faster diffusion speed.

CONCLUSION
The global trend of cross-domain knowledge diffusion from science to policy has been increasingly evident, especially in light of the COVID-19 pandemic. Many countries heavily rely on scientific papers for policy-making. To explore the cross-domain knowledge diffusion from science to policy, this study uses policy data with citation relationships from the Overton database. Diffusion strength, diffusion breadth, and diffusion speed indicators are proposed to quantify the characteristics of cross-domain knowledge diffusion from science to policy. The analysis is conducted from three aspects: data distribution of diffusion characteristics, analysis of diffusion strength and breadth, and analysis of diffusion speed, and several significant findings has uncovered.

Firstly, the intensity and breadth of cross-domain knowledge diffusion from science to policy follow a power-law distribution, indicating that only a handful of papers have a profound impact and receive extensive citations. This can be attributed to the exceptional contributions made by these papers in problem-solving, theoretical advancements, empirical analyses, or their focus on topics of great social importance. Moreover, these influential papers are often published by prestigious universities, renowned scholars, and reputable journals, granting them heightened visibility and broader dissemination channels, thus reinforcing their strong diffusion intensity and breadth.

Secondly, the speed of cross-domain knowledge diffusion adheres to a logarithmic normal distribution, signifying considerable variability in the rate of dissemination among papers, with some spreading more rapidly than others. This variability may stem from the urgency of the issues addressed in these papers or the direct practical value of their research methods and findings for policy-making. In essence, these observations highlight the nonlinear and uneven nature of knowledge diffusion from science to policy. A small number of highly impactful and extensively cited papers wield significant influence on policy, aligning with the fundamental principles of the Matthew effect.

Furthermore, a strong positive correlation exists between diffusion intensity and breadth, indicating that highly cited papers often have a broader impact. Conversely, there is a significant negative correlation between diffusion speed and breadth, as well as intensity, suggesting that papers with faster dissemination tend to have relatively lower breadth and intensity. This may be attributed to rapidly spreading papers exerting unique influence in specific fields or policy topics, rather than having widespread impact across different domains or subjects.

Finally, the research reveals the variations in diffusion characteristics and content across different fields. Papers with the highest diffusion intensity and breadth predominantly originate from the field of economics, whereas those with the fastest diffusion speed primarily come from the field of medicine. Papers with the highest diffusion intensity and breadth primarily focus on social sciences, encompassing climate issues, employment challenges, public health concerns, and social development problems. On the other hand, papers with the fastest diffusion speed mainly emerge from the fields of medicine and life sciences, followed by social sciences, with a particular emphasis on public health issues and social development matters. These observations underscore the disparities and importance of research outcomes from diverse disciplines in the cross-disciplinary diffusion of knowledge from science to policy. Economics papers exhibit higher citation and diffusion levels due to their close connection with socioeconomic issues in policy-making. Papers from the field of medicine experience faster diffusion due to their direct focus on human health and public health matters, especially during emergencies and disease outbreaks. Meanwhile, papers from the field of social sciences address social problems and human behavior, playing critical roles in policy-making and societal transformations, thereby demonstrating higher diffusion intensity and breadth.

This study discusses the characteristics of cross-domain diffusion of science to policy and contributes to the understanding of the two-way interaction between science and policy, which has never been studied before. It also provides theoretical guidance for science to help with policy-making. However, the research results may be biased due to the limited coverage range of the data, which mainly includes policy data from Europe and America and may not fully represent the global data. Meanwhile, 2021 is the year of the global pandemic of COVID-19, and the findings of this paper may have been influenced by this phenomenon.

ABSTRACT
The goals of open science are driven by policies requiring data management, sharing, and accessibility. One way of measuring the impact of open science policies on scientific knowledge is to access data that has been prepared for re-use. But how accessible/available are data resources? In this paper, we discuss a method for exploring and locating datasets made available by scientists from federally funded projects in the US. The data pathways method was tested on federal awards. Here we describe the method and the results from analyzing fifty federal awards granted by the National Science Foundation to pursue data resources and their availability in publications, data repositories, or institutional repositories. The data pathways approach contributes to the development of a practical approach on availability that captures the current ways in which data are accessible from federally funded science projects—ranging from institutional repositories, journal data deposit, PI and project web pages, and science data platforms, among other found possibilities. This paper discusses some background and motivations for such a method, the method, research design, barriers encountered when searching for data resources from projects, and how this method can be useful to future studies of data availability.

KEYWORDS
Data availability; Open Science Policies

INTRODUCTION
Several national policies and legislative efforts in the last few years speak to the significance of machine-actionable data management and availability. For instance, the CHIPS Act passed in 2022 mandates that awards granted by funding agencies make data available for sharing. The now well-known “Nelson Memo” from the Office of Science and Technology Policy (OSTP) office states that data immediately be made available upon publication. These efforts, and others globally, speak to the significance—and policy momentum—building around the aims of the open science movement that seeks to open and share science data to foster innovation. Federal policies aim to make data available at the end of projects as a promise of most efforts. But data from grants may end up in any number of places—personal websites, publication venues, cyberinfrastructures, and data repositories. Presumably, data from research funded by national funding agencies are a public good and available for access.

For researchers interested in research data management, the role of the professional data librarian, and data reuse the rise of policies to make data available has introduced a new avenue and problem: the accessibility to datasets that are considered a public good. Data accessibility is a combination of where to find data, how to find data, how data is structured, and how data sources link together on the web. Policies that mandate data availability thus raise an interesting question for LIS scholars: if policies require availability, how exactly are data resources found and accessed? This paper elaborates on one such method: data pathways.

In response to the growing efforts by federal agencies that pressure researchers to make data available and the distribution of data into many venues, in this paper, we discuss the development of the data pathways method to locate the availability of data resources generated from federally funded grants. The data pathways approach presented here aims to build out prior work that connects the location of data to the data management plans written for federally funded awards (Bennett et al., 2021). The paper reports on locating the most common “paths” of access to data resources, most typically datasets (though other data resources are possible).

The demand to understand how accessible data are from federal grants from the pathway approach has emerged from an interest in ascertaining how researchers comply with federal policies including the resources used to make data available. The FAIR principles, endorsed by Research Data Alliance (RDA) in 2018, outline four guidelines to support the reuse of scholarly data, including Findability, Accessibility, Interoperability, and Reusability. What makes these principles distinct is their focus on machine action, as the authors of the FAIR principles explain: “Distinct from peer initiatives that focus on the human scholar, the FAIR Principles put specific emphasis on enhancing the ability of machines to find and use the data automatically, in addition to supporting its reuse by individuals,” (Wilkinson et al., 2016). The FAIR Principles are operationalized into the FAIR Data Maturity Model which explicitly states that for data to be FAIR that “rich metadata is provided to allow discovery” and even says...
that a dataset should be evaluated upon “how much metadata is provided and how well the provided metadata supports discovery” (RDA 2020, p.12-13). However, our findings and the findings of our previous research on data pathways (Bennett et al., 2021) demonstrate that discovery remains a vexing challenge and suggests that more specificity around the discoverability of data may be essential if FAIR is to achieve its goals. Using the methods outlined here shows that machine actionability is likely to be challenging if the data cannot be found and accessed. Findability of data is constrained by web information retrieval.

In this data pathways method, the process to search for data and the information ecosystem for data storage and retrieval is equally as important as what data are found. This approach assumes that there are multiple realities for data availability governed by a combination of social and technical factors including but not limited to the scientific research project, the institutional context of research including funding and labor dedicated to data management, security issues of data; retrieval issues such as access, download, format, and software interoperability. This approach also sheds early light on information retrieval issues to search and find data resources.

LITERATURE REVIEW
Data from federally funded projects is available via publications, domain repositories, project websites, and platforms. But data availability is not guaranteed, and many factors influence (and impede) data availability. Data availability measures whether or not datasets are available from research projects. Several research studies have analyzed data availability using qualitative methods that assess how, where, when, and what factors influence the availability of scientific data. Such qualitative approaches have ranged from survey methods (Kim & Adler, 2015; Kim & Stanton, 2013; Tenopir et al., 2011), email request studies (Savage and Vicker, 2009; Hardwicke et al., 2018; Tedersoo, Küngas, Oras et al., 2020), and document analysis of scientific publications where authors agree to make their data available (Federer, Belter, Joubert et al., 2018; Graf et al., 2020) to examine the loop between what is said about data availability and the realities of whether data are available.

Survey methodology has produced a body of knowledge about how policies influence data sharing. Survey methods cast a wide net of researchers to determine whether the policy is a factor that shapes sharing and availability. What is learned from this literature is that researchers are more willing to provide data upon request (Tenopir, Allard, Douglas et al., 2011). Policies impose different kinds of pressure to make data available. Journal policies, disciplinary norms, and scholarly altruism are three factors that positively impact sharing (Kim and Stanton, 2013).

In contrast, normative pressures by funding agencies and perceived career risk had no association with data sharing (Kim and Stanton, 2013). In a similar study drawing on survey methods, individual attitudes may be at odds with journal and government mandates regarding data availability (Kim and Adler, 2015). Survey methods teach us that policies do not equally motivate researchers to make their data available.

Document analysis measures compliance with federal and journal policies that require data availability. Document analysis is a method that solicits planning documents from scholars to assess plans to make data available. A content analysis of data availability plans showed that compliance increases over time and that sharing data via publication continues to be the norm (Federer, Belter, and Joubert, 2018). Similar to the findings above, another study that analyzes statements found that most researchers plan to make their data available upon request (Graf et al., 2020). Document analysis provides insights into how scholars plan to make their data available but not whether they enact those plans.

Other studies utilize a combination of document analysis and email studies to examine data availability. Studies in this area aim to close the loop between what is said about data availability and the actual location of the data. One study found that despite PLOS One’s journal requirement to make datasets available, many authors did not provide access to data (Savage and Vicker, 2009). Similar findings emerged from a larger sample of publications from a popular psychology journal. Scholars analyzed data availability statements pre- and post-policy implementation of a data availability policy. Researchers searched for datasets listed in data availability statements but were largely unsuccessful (Hardwicke et al., 2018). The study found that post-policy compliance increased data availability, but data reusability remained low due to the quality of curation. In another recent study, researchers analyzed data availability statements from high-impact journals by looking for the datasets from publications and then contacting the data creators (Tedersoo, Küngas, Oras et al., 2022). Those researchers also concluded that data availability statements do not provide an accurate snapshot of how to access data (Tedersoo, Küngas, Oras et al., 2022).

Overall, the data availability research from scholarly communication researchers like Tenopir, Kim, Hardwicke, and Tedersoo and from scientists themselves is clear: scientists claim to want to share data and to comply with policies, but their willingness to share when asked directly is not as universal. Thus, measuring the health of data availability could benefit from introducing another method.
This paper shifts from engaging with scientists via survey, email, or document collection to finding the data ourselves. We contribute to a critical analysis of data availability, in which data availability is approached not as a measure of compliance but as a realistic approach to assessing web retrieval of data.

**DATA PATHWAYS: RESEARCH DESIGN**

We investigate data availability as an information retrieval problem. Our pragmatic approach to data retrieval focuses on analyzing the pathway to find datasets from research funded by the NSF. The NSF is an independent federal agency established in 1950 that maintains a large portfolio to fund basic and applied research. In 2011, the agency implemented a data management plan policy that required all proposals seeking federal grants to describe how data would be managed and made available after the completion of the research project (Pasek, 2017). Thus, we assume that data will be available from the project.

The research design of our study aims to trace a pathway to find data. We draw on information provided by the NSF to get the context of a research award and the information necessary to conduct a search. To test the retrievability of data, we start by collecting information about federal research grants from the NSF. The NSF provides historic information about awarded projects (such as the PI’s name and their institution) including links to final reports, outcomes, and increasingly products like publications or data resources that result from the completion of awards. We assume that federally funded awards generally (but not universally) will result in scientific knowledge production and that data will be available for those outputs. Those outputs include publications, information resources, samples, specimen materials, software, and code that will be preserved and made accessible.

To pilot the pathway method, we had a team of six: the second author was one primary coder, the first author was the second coder who also served as a “code lead” for the synthesis, and the last three authors were external members for vetting and review. First, the external members developed a list of grants from the NSF. An awards list from the NSF was downloaded from five research areas: Civil Mechanical, Manufacturing and Innovation (CMMI), Division of Biological Infrastructure (DBI), Oceanography (OCE), Secure and Trustworthy Cyberspace (SATC), and Science and Technology Studies (STS). Eight awards were randomly selected from each funding area from 2011-2018. In total 56 grants were analyzed.

![Figure 1. This screenshot from the nsf.gov features a successfully funded research project (Award # 1226726) and metadata about the nature of the research.](image-url)
Figure 2. This screenshot features award #1226726. The abstract and publications produced as a result of this research are listed on the summary page. Upon completion both publications as a result of the award and project outcomes report are published below the award information. To find different pathways to potential datasets, we leveraged critical information from project award pages to seek out and find different data products.

Following the awards selection, coders were given instructions to find data from the award. The coders relied on the NSF award search page that lists a series of publications produced as a result of the research and also contains a project outcomes report (Figure 1 and Figure 2). The pathways method relied on the documentation available to the public to search for awards funded by the independent funding agency. Coders used information from the awards page to then observe web retrieval of data. This included focusing on what information was available to find data, the search that was conducted, the websites visited, the links that were clicked, success or unsuccess of finding data, and any challenges that arose when looking for data.

RESULTS: PATHWAYS PRODUCED

In this section, we describe the five pathways that were defined by the coders during their efforts to search for federal datasets (Figure 3). Coders utilized all five pathways to ensure all searches were exhausted to find data. All five pathways originate from the information stated on the nsf.gov awards page. The first pathway focused on finding data from the publication listed on the awards page. The second pathway focused on the principal investigator PI(s) as the source of data retrieval. The third pathway focused on the project level strategy to retrieve data. The fourth pathway focused on the organizational host or the network of scientists as the site for data retrieval. The fifth pathway defined a search strategy based on the keyword search related to the science project on web engines. Lastly, a location perspective was taken on data retrievability. Coders focused on the institutional repository as the site to retrieve data.
Figure 3. This pathway is an iterative workflow of the possible data paths that coders took to find datasets from federally funded awards. Coders delineated five pathways or search strategies. Each strategy began with information provided from the NSF awards page. The information from the NSF was then used to conduct searches. Each pathway represents how coders took the information from the awards page and used it to search for datasets.

Pathway 1: Publication Pathway
The most common pathway found by coders to find datasets was the publication-centric pathway. This pathway began by collecting information or DOIs from publications on the award page. From there, coders used several strategies to find datasets in publications. Coders used institutional databases to search for the publication title and DOIs using their search bars. When coders could not find journals through authoritative sources, coders used the search engine Google or Google Scholar. Coders noted whether publications were open access or gated by a paywall. Coders assessed publications for datasets or statements about the availability of datasets. Coders took information from publications and used the information to search for datasets. Coders documented how journals organized publication records online to ascertain if any pattern led to data resources. Coders found links to data in the acknowledgments section, supplementary materials, and the data availability statement.

Pathway 2: Data Creator Pathway
A second pathway coders defined was a data creator pathway. This pathway was used when no publications were listed on the awards page. The data creator pathway began with the PI name found on the awards page. Coders grabbed information about the PI including name and affiliation. This search typically produced links to a university or college webpage featuring information about the PI. In some cases, a link to a personal webpage hosted by the PI was found on the institutional webpage. Coder’s searched both web pages for evidence of data created from the award. While institutional webpage profiles did not result in datasets, personal web pages in some cases presented links for data to be downloaded. Faculty pages also listed other kinds of information that allowed coders to search for data such as curriculum vitae, research project summaries, lab members, awarded grants, and publication citations. Other information not included by the NSF award page was retained. Coders were led to other website such as Google Scholar profile pages, ResearchGate profile pages and other aggregating websites. These websites are also useful to see if datasets are made available.
Pathway 3: Project Pathway
If coders did not find data from the publication pathway or the data creator pathway, the project pathway was conducted. Coders extracted the project name and/or project facility and used them as keywords to search projects websites. In some cases, facilities and project websites contained publications that would be searched if they were not featured already on the nsf.gov website. Information from project websites were retained to conduct searches.

Pathway 4: Phenomenon-Centric Search
Another approach defined by the coders was a phenomenon-centric approach. This pathway focuses on searching for datasets based on the scientific research topic. Coders extracted keywords about the research from the abstract on the awards page. Those keywords were entered into a search engine to find repositories or networks of researchers working on a similar research topic.

Pathway 5: Search by Institutional Repository at PIs organization
Lastly, coders defined an institutional repository approach. Institutions hold a wealth of outputs from research and preserve those outputs. Coders went to institutional repositories adjacent to the home institution of the PI. Coders searched within institutional repositories using the PI’s name or project. Institutional repositories typically are not the most fruitful sites to find data resources but occasionally yield additional publications. In some cases, an institutional repository may hold datasets from individuals affiliated with the award such as junior scholars, research assistants, and doctoral students.

Summarizing pathways
The data pathways approach provided several insights in searching, locating, and identifying data resources from projects published in the NSF awards database. The pathways reflect the rhizome-like/peripatetic nature of searching for datasets. The different pathways to finding data from federal grants were comparable to the root system of rhizomes. The mother node in this case was the information located on the NSF awards page. The NSF awards page provided the information to go to other nodes such as journal database or a PI’s website. The aggregate information provided by the NSF was a crucial part to the pathway. If few details were provided, coders would have to find information from the web and then seek out nodes towards datasets. The information provided by the NSF is vital to begin the search for datasets. From there the pathways were comprised of many nodes (webpages from organizations, publications at databases, database for publications to repositories, data publications to cloud services, and/or PIs webpages). In some cases, the nodes led to other nodes and in other cases the nodes were dead ends.

Comparing pathways
The most common pathway that led to finding datasets from federal awards was the publication pathway. We observed that publications listed on the awards page contained links to the storage sites for the datasets and/or availability statements to ascertain where datasets are located. In successful cases, the publication listed on the awards page was entered into the database. Once the publication was found, an embedded link in the publication could lead out to the dataset. This link led to either a data repository (such as GenBank) or a federal agency repository. In some cases, a data availability statement directed readers to a repository or anticipated deposit site. The link or the statement to the dataset could be located in the supplementary materials section, the data availability section, or the acknowledgements. In the acknowledgements section, in some cases, PIs listed more than one source of funding that contributed to the publication. This was the most parsimonious pathway to find data.

Another successful pathway we observed to find a dataset was to head to the PIs website. Once a publication was searched and no links were found, coders went to the PIs page to discover datasets. Datasets were triangulated by reading the proposal award. In one case, we found a sophisticated case of data availability. A PI had datasets available for download on their lab webpage. This PI requested that a download form be completed before access was given to the requestor.

The least successful path were pathways 3, 4, and 5. The coders assumed that project level and organizational level websites would produce a list of datasets but to the contrary, such websites rarely contained datasets but instead featured publications as the outcomes from the project and/or facility.

Pathways and the Location of Data
We found differences in data availability across research areas (Table 1). We found datasets from approximately four out of ten awards from oceanography and biology. Awards analyzed in the area of security research resulted in only three awards that made data available. No awards from engineering and science and technology studies resulted in the retrieving data. In total, data was available from 11 awards out of the 56 awards that were analyzed.

We found a combination of storage sites for data. Data was found in domain repositories; generalist repositories; platforms like GitHub and Google Drive; and institutional repositories at universities. Coders use pathway one, two and three to find data.

Table 1. Research areas had varying levels data availability. In total, datasets from 11 out of 50 awards were found. Data was made available via cloud based services, data repositories, institutional repositories, or supplemental materials in publications.

Helpers Along the Way
We observed several helper websites that provided information on where to find data. Helper websites included journal publishers, science aggregating websites, and google scholar. Journal publishers provided links to the different sections (such as introduction, literature review, figures and tables, results, acknowledgements, supplemental materials etc.) of the journal article. Coders could jump to sections in order to look for data sources or links to data sources. DOIs were helpers that let coders know that publications listed on the NSF award page were connected to the publication found in the database. The quest to find data was very dependent on whether embedded links worked.

We found websites that aggregated NSF funding and publications by researchers augmented search processes. For instance, we encountered science aggregating websites like Dimensions.ai (See https://www.dimensions.ai, a website hosted by Digital Science). This website was encountered during a google search for a publication. On this site, we found awards, patents and publications related to an individual researcher. While the platform provided a wealth of information, we were unsure how the software was compiling information from the NSF awards database.

We also observed that the NSF Public Access Repository (NSF-PAR) provided a repository of publications from funded awards. This helper website was encountered via Google Search. It was not evident that these publications were available on the NSF’s repository through the awards page.

Obstacles Along the Way
Many obstacles were encountered during the pathways approach. Coders found outdated web pages, deadlinks, technical issues around formats for storing data, closed access to publications, and the lack of certainty around PI affiliation, and the lack of certainty around the individuals on the grant as obstacles that hindered our search for data.

Webpage and Links
One of the most common challenges we observed were issues related to longevity and persistence of web resources. Outdated webpages and outdated internal links were common on PI websites hosted by .edu domains. Some PI websites were clearly not updated and were relics of the past. Broken internal links led to “not found page”. Interlinks, backlinks, and hyperlinks were not always reliable.

Inaccessibility to Journals
Coders encountered limited accessibility to journals associated with publications. Coders observed that that despite having access to sophisticated resources hosted by large universities, some journals were not accessible. Coders tried to engage in workarounds to find publications. Publications were accessible via Google Scholar, the PIs personal webpage, the PIs or co-author’s webpage on researchgate.com. Publications were also available via third part websites.

Data from Unique Outputs
Many awards produced a range of outputs that complicated the pathways to find data. Coders became well versed in finding data statements or look for data in the supplemental material from journal articles. However, coders were not
sure how to search for data from outputs such as an online museum, a video and/or a book. Coders went to the PIs websites and institutional repository to search for data with no success.

**Data Formats**
When coders did find datasets, proprietary data formats from software prevented access to the dataset. In another case, data files were corrupted and not accessible.

**Institutional Affiliations**
Coders found the information from the NSF award’s page to reflect the information at the time of the grant. Searches were complicated outdated information provided by the NSF. Coders found several webpages for one PI and figured out that some PIs had moved to another institution. PIs also had more than one webpage. The most PIs had a webpage by their institution and an embedded link to their person webpage.

**Generative Aspect of Grant Funding**
Another obstacle coders encountered was understanding the full scope of the research project and the individuals involved on the project. Coders observed that grants led to many different kinds of research projects with many different individuals. PIs listed on the NSF awards page were not always the first authors of publications, and in some cases PIs were not even listed as authors on the publications from the award. This made it challenging to triangulate how other researchers were involved on the award and whether coders missed publications from other researchers affiliated with the award. Exhaustive searches were completed on all the individuals that were listed as first authors in the publications.

Coders also found that data retrievability was based on first author of a publication. Coders found that the point of retrieval for a dataset was the first listed author on a publication. Coders used this strategy to conduct a pathway search on all listed first authors of publications listed on the awards page. In one case, the first author was a graduate student advisee of the PI. The award funded that student’s dissertation.

Coders found that in the acknowledgements section of some publications, first authors listed multiple funding sources that led to the publication. Coders had to ascertain whether datasets from publications were governed under the NSF or other agencies that provided funding.

**Limitations**
The data retrieval pathways we defined and summarized has a few limitations. We developed a standardized approach here but believe that a closer look into this process is warranted. A more systematic design to follow pathways could be beneficial. We think the approach could be improved by developing map of the retrieval pathways and visualization networks. Further, we only tested 56 awards, more awards from different research areas need to be tested in order to delineate pathways. A larger sample size across many research areas could provide deeper insights into the pathways of how data are accessed. We also did not contact individuals to get access to data. This was another pathway that could be explored.

**Discussion**
By applying the pathways approach to find data, our findings suggest that data retrievability is a complex, time-consuming task. The findings are relevant to the growing interest to apply machine-actionability to data availability by federal agencies and stakeholders. Machine-actionability refers to the use of a structured, digital system of information organization for data planning and availability for machines to be able to read. A machine-actionable plan is based on the logic of coordinating data availability through automation. Principles like FAIR aim to make data first class objects. Our findings showcase that this logic may be challenging to implement.

First, automating findability is challenged by the distributed network of web services as sites for data storage. Increasingly datasets are found on the web outside of formal repositories such as a researcher’s website or a project’s website. Our work shows that web resources are persistent over time. Some webpages are abandoned or change across time and place. While datasets are increasingly found on the web most data are still embedded in publications. Access to publications is vital to finding datasets from federal grants. Third, an award from the NSF is generative. PIs extend funding to many individuals across many projects that result in many data stewards. Grant funding may be pooled with other funding. This complicates who has jurisdiction over the data and who can make it available. Further, grant information provided from the funding agency is not up to date. Searches need to conduct an extra layer of search to get the details of a grant correct before searching for the data. This summary showcases that machine actionable data is only possible if all of the identifiers and the underlying infrastructure that change across time and space is accounted for and managed.

**CONCLUSION**
Schatz (1997) once wrote “immediate access to all scientific literature has long been a dream of scientists”. This dream is now alive and well at the NSF regarding datasets. We tested this aspiration at the NSF by putting forth a
data pathways method. In future work, we plan to further the pathways method by creating visualizations of different paths to understand the bottlenecks and passages to data.

ABSTRACT
Many Black Americans expressed skepticism and hesitancy about the Covid-19 vaccine. The objective of this research is to examine whether there is a relationship between Covid-19 vaccine status, Covid-19 vaccine knowledge, and information seeking about the coronavirus. A national online questionnaire of 222 Black identified individuals completed the instrument in the Summer of 2021. We conducted data analysis using ANOVA and nonparametric correlation tests among the variables. Findings show that individuals who have received the COVID-19 vaccine exhibited greater COVID-19 vaccine-related knowledge compared to people who declined the vaccine, or were hesitant adopters. There is no significant difference in the level of knowledge between those who are hesitant about the vaccine and those who declined it. Finally, there is a moderate positive correlation between COVID-19 vaccine knowledge and engagement in COVID-19-related information seeking. We conclude with strategies to improve the Black American health information environment by way of practice, policy and action.

Information seeking; information use; health information; Covid-19; vaccine knowledge

INTRODUCTION
The Association for Information Science and Technology Annual Meeting 2023 posits “how can we release the transformational power of information research and translate our findings into positive differences to how lives are lived?” We suggest the initial step in this effort is to produce information research that centers diverse communities and their information practice. When certain populations are overlooked, marginalized, and/or erased, our distinctive disciplinary domain will never realize its potential to transform the human condition across diverse populations and geographies. In the United States the ongoing novel coronavirus pandemic has had a disproportionate impact on the Black/African American community. During the early phase of the pandemic, for example, Black residents in Chicago comprised over 50% of COVID-19 cases and over 60% of related deaths. In the southern state of Louisiana over 70% of the COVID-19 deaths were among Black Americans however; the Black population in both jurisdictions was no more than 32.2% (Yancy, 2000). This unbalanced disparity is not wholly unexpected as marginalized populations have “historically borne a disproportionate burden of illness, hospitalization, and death during public health emergencies, including the 2009 H1N1 influenza pandemic and the Zika virus epidemic (Akintobi et al., 2020). While information science researchers have begun to study various information practices related to the novel coronavirus spanning New York denizens, public library leaders, and Black college students in the United States (Bossaller, et. al 2022; Stewart, 2021; Wu 2021) there is very little research in information science that centers the information behavior of the general Black American population and the current pandemic.

Moreover, the current paper is a baseline study where we seek to investigate the relationships among COVID-19 vaccine status, levels of COVID-19 vaccine knowledge and Covid-19 information seeking among Black Americans. The paper concludes with a discussion of targeted strategies to increase information dissemination.

BACKGROUND
Black Americans were one of the most hesitant populations to accept a COVID-19 vaccine (Thompson et al., 2021; Mackey et al., 2021; Willis et al., 2023). Such hesitancy, according to research literature, is grounded in historical and social inequities, which likely intersect with geography and outcomes experienced by the community. A meta-analysis of COVID-19 vaccine hesitancy found that nearly 42% of the Black community were vaccine hesitant; this is in contrast to a general hesitancy rate of 26.3% in the United States, the study found (Khubchandani, J., & Macias, Y., 2021). Vaccine hesitancy is the focus of several studies that seek to better understand factors that may influence Black Americans reluctance to vaccinate. Savoia and colleagues (2021) found racial discrimination as one significant factor; Black participants had a 21% higher odds of vaccine indecision versus individuals who did not report these experiences with discrimination. Other factors are a relative lack of trust in “government and the medical professionals” notably the hesitancy here is “more about the government's motives rather than its competence (McFadden et al., 2022). Vaccine related behaviors and trust in information sources are additionally likely factors in vaccine hesitancy. Woko, Siegel, and Hornik (2020) found that Black participants held “less positive beliefs about vaccinations” and this ethos correlated with vaccine intentions. Curiously however, the study notes that trust in information resources is correlated to vaccine beliefs but low trust levels in COVID-19 information, does not
explain vaccine hesitancy in Black participants; this outcome suggests there are other factors at play in the lived experiences and information behavior and practices of Black Americans.

Previous studies have suggested that “knowledge” may form “an important factor shaping” decisions about vaccinations; misinformation about vaccines and any impending “consequences of vaccinations” can affect the decision-making process across a multitude of vaccines for both children and adults (Zingg and Siegrist, 2012; Swed, S. et al 2023). A recent study highlighted the stark disparity in COVID-19 knowledge and attitudes among racial/ethnic groups in the United States. Generally, people of color had lower scores than white Americans. For example, Black American knowledge scores averaged 14 out of 18, which the researchers defined as low; in contrast to 16 for Whites which denoted high. Additionally, 70% of whites had a high COVID-19 knowledge score; only 35% of Blacks had similar scoring (Alobuia et. al, 2020). We encountered very few studies, in information science, situated on Black information seeking practices related to the coronavirus. Stewart’s 2022 analysis of Black American college students found that health information seeking related to COVID-19 coalesced around social media and the internet. Symptoms, protective measures, at risk populations and the coronavirus’s impact on the Black community were the primary information needs. Similar results were noted in another study of minority populations’ information seeking found that among Black Americans cultural identity affected the community’s information perception on Covid-19 (Kim, Cham-Olmsted, and Chen 2022). Interestingly, the study also found that “perceived information value was positively associated with vaccination status” among participants (Kim, Cham-Olmsted, and Chen 2022). There is currently a dearth of knowledge on Black American information behavior in the context of the novel coronavirus. Therefore, in this paper, we propose to investigate relationships among COVID-19 vaccine status and COVID-19 vaccine knowledge and relationships among COVID-19 vaccine status and COVID-19 information seeking among Black Americans.

RESEARCH METHODS
We conducted an online survey of 222 Black identified individuals in June of 2021. A quantitative data analysis was performed via analysis of variance (ANOVA) and nonparametric correlation tests to identify any significant relationships among the variables: COVID-19 vaccine status, levels of COVID-19 vaccine knowledge, and COVID-19 related information seeking.

Study participants
All individuals were African American/Black, resided in the USA, are older than 18, and voluntarily participated in the study through the Qualtrics Panel Services. Among the 222 respondents who identified their gender, there were 110 male respondents (49.55%) and 112 female respondents (50.45%). The respondents represent a wide range of age groups, including 19 or younger (24 respondents, 10.81%), 20-29 (87, 39.20%), 30-39 (57, 25.66%), 40-49 (22, 9.90%), 50-59 (18, 8.10%), and 60 and older (14, 6.33%). In terms of educational background, the participants include those with a high school degree or less (68, 53.04%), some college education (74, 38.14%), a bachelor's degree (34, 17.53%), a master's degree (12, 6.19%), a doctoral degree (2, 1.03%), and a professional degree such as a JD or MD (4 respondents, 2.06%). Of the total of 222 respondents, 28 did not provide information on their educational background.

Measures and null hypotheses
Our research question was addressed using three measures. In this study, we define COVID-19 Vaccine Status (VAX Status) as the status of individuals' COVID-19 vaccinations. To measure this variable, participants were asked to indicate their vaccination status by selecting one of three response options: Vaccine Received, Declined, or Hesitant at the time of survey completion. COVID-19 Vaccine Knowledge (VAX_KNWL) is defined as individuals' level of knowledge about the COVID-19 vaccine. In order to measure individuals’ knowledge about COVID-19 vaccination, we utilized a one-dimensional scale consisting of nine items which was originally developed by Zingg and Siegrest (2012) to evaluate general vaccination knowledge. Our scale was developed based on the 'Myths and Facts about Vaccines' guidelines established by the Centers for Disease Control and Prevention (2023). Participants were presented with nine items and asked to indicate their response as either True, Do Not Know, or False for each item. To analyze the data, we assigned one point to participants for each correct response and zero point for incorrect or 'do not know' responses. COVID-19-related Information Seeking (InfoSeek) in this study refers to participants’ pursuit of COVID-19-related information and was measured with their responses to a 5 Likert-style scale (Strongly disagree to Strongly agree). To address our research question, we tested the following two null hypotheses:

H₀₁: There no significant differences in COVID-19 vaccine knowledge levels among the 3 groups of people (vaccine received; vaccine declined; and vaccine hesitant) in the Black community?

H₀₂: There is no association between people's COVID-19 vaccine knowledge level and their information seeking behavior.
DATA ANALYSIS AND RESULTS
Out of the 222 survey responses received, 220 were included in the analysis, as two were excluded due to incomplete responses. To examine the relationship between COVID-19 vaccine knowledge and vaccine status (vaccine received; vaccine declined; and vaccine hesitant), a one-way ANOVA was conducted. Table 1 shows that the mean of the Received group is noticeably higher (\( \bar{X} = 4.1439 \)) than both the Declined group (\( \bar{X} = 1.4231 \)) and the Hesitant group (\( \bar{X} = 2.2903 \)). The normality of the data was assessed using a Shapiro-Wilk test. The test showed that the data were normally distributed (W = 0.903, df = 220, \( p < .001 \)). The standard error, which is a measure of the variability of the sample means, was found to be small for all three groups. This suggests that the means for these groups are precise estimates of the population mean.

Our ANOVA analysis (see Table 2) found significant differences in mean scores for COVID-19 vaccine knowledge levels across the three groups. Specifically, the results indicated a significant main effect of group, with an F-value of (2, 217) = 19.128, \( p < .001 \). This F-test indicates that the model explained a significant amount of variance in vaccine knowledge level, \( \eta^2 = .15 \). The results revealed that the Received group had statistically significantly higher mean score (M = 4.4139, SD = 2.8269), \( p < .001 \) than the Declined (M = 1.4231, SD = 2.0625), \( p < .001 \) and the Hesitant (M = 2.2903, SD = 2.0597), \( p < .001 \). \( H_0 \) was rejected. Additionally, Tukey HSD post-hoc test was performed to examine significance of pair-wise group comparison (Table 3). The HSD test results showed that there are significantly difference in mean scores between the Received group and both the Declined group and the Hesitant group. However, there was no significant difference in mean scores between the Declined group and the Hesitant group.

Table 3. Tukey’s HSD Test for Pair-wise Comparison of Mean Differences

To examine the relationship between COVID-19 vaccine knowledge and information seeking, we first examine the match of these two variables. We used PP Plots (probability-probability plots) to compare the cumulative distribution function (CDF) of participant’ COVID-19 vaccine knowledge level with their information seeking, where both variables follow normal distribution (Shapiro-Wilk test for Information Seeking: W = 0.943, df=220,
p<.001). As Figure 2 (COVID-19 vaccine knowledge level) and 3 (Information seeking) show, the plots for both participants' knowledge levels and information seeking show minimal deviation from the ideal cumulative distribution functions (CDFs), indicating a close match between the observed and expected probabilities. The shapes of the distributions of the two plots are similar and well-matched, enabling a meaningful comparison between these two variables. Figure 4 demonstrates the relationship between COVID-19 knowledge levels and information seeking.

Figure 2. P-P Plot of COVID-19 Vaccine Knowledge

![Figure 3. P-P Plot of Information Seeking](image2)

Figure 4. Relationship Map between COVID-19 Vaccine Knowledge and Information Seeking

![Figure 4. Relationship Map between COVID-19 Vaccine Knowledge and Information Seeking](image3)

We used Spearman's rho to calculate the correlation coefficient for ranked data. (Table 4). Our results revealed a moderate positive correlation ($r_s = 0.309, p<0.001$) between individuals' COVID-19 vaccine-related knowledge levels and their COVID-19-related information seeking behaviors, leading us to reject $H_02$. Our findings suggest that individuals with higher levels of COVID-19 vaccine knowledge tend to engage in more COVID-19-related information seeking behavior, including paying closer attention to COVID-19 news, searching for more information, consulting multiple sources, and actively seeking out COVID-19-related information.
Overall, people in the Black community who have received the COVID-19 vaccine exhibit a greater COVID-19 vaccine-related information compared to those who declined the vaccine or are hesitant about it. There are clear differences in the level of knowledge about COVID-19 vaccines between people who received the vaccine and those who are hesitant to receive it or declined to receive it. Furthermore, the differences in knowledge levels between those who received the vaccine and those who declined it are also significant. However, there is no significant difference in the level of knowledge between those who are hesitant about the vaccine and those who declined it. There is a moderate positive correlation between COVID-19 vaccine knowledge and engagement in COVID-19-related information seeking behavior, indicating that individuals with higher levels of COVID-19 vaccine knowledge are more likely to seek out information related to COVID-19.

**DISCUSSION**

The results of the study indicated several important findings. First, individuals in the Black community who have received the COVID-19 vaccine exhibit greater COVID-19 vaccine-related knowledge compared to those who declined the vaccine or are hesitant adopters. There are statistically significant differences in the level of knowledge about COVID-19 vaccines between people who received the vaccine and those who are hesitant to receive it. The differences in knowledge levels between those who received the vaccine and those who declined it are also significant. However, there is no significant difference in the level of knowledge between those who are hesitant about the vaccine and those who declined it. There is a moderate positive correlation between COVID-19 vaccine knowledge and engagement in COVID-19-related information seeking behavior, which indicates that individuals with higher levels of COVID-19 vaccine knowledge are more likely to seek out information related to COVID-19.

As mentioned earlier in the paper, Black Americans were the most vaccine hesitant racial/ethnic demographic in the United States. Pre-pandemic health inequalities and employment segmentation that disproportionately funnels many Black Americans’ into public facing jobs that are labeled as “essential workers” resulted in a tripartite social reality of over represented Covid-19 diagnoses, hospitalization, and deaths (Millett et. al, 2020). Results from this study suggest two information subpopulations; one, the vaccinated, has high COVID-19 vaccine knowledge and high information seeking. Conversely, the other, composed of vaccine decliners, has low vaccine knowledge and low information seeking. While the current study did not examine how or where vaccine hesitant and declining individuals acquired their information, our results suggest this subpopulation may likely exist in an information environment that is outside of mainstream/ traditional information channels. We propose several strategies that can be leveraged by diverse entities to help propagate critical information to increase health information knowledge and aid information seeking during crisis/ emergency health episodes.

To enhance emergency communication during health crises such as the COVID-19 pandemic, local and regional governments can consider adopting a wireless emergency alert service (WEA) that delivers audio-visual information directly to mobile phone users. This technology is already widely used in the United States to notify people about extreme weather conditions and AMBER alerts for finding abducted children. By leveraging this service, governments can disseminate critical information about community infection levels, local vaccination sites, and links to reliable COVID-19 fact sheets and mitigation strategies. This mobile outreach approach provides a fast and authoritative means of delivering information to individuals who may not access mainstream health information channels. After recent tornado damage, for example, the Governor of Arkansas, sent out a text message that serves as a good example of how emergency communication can be leveraged during a crisis (Figure 5). This message illustrates how governments can use mobile outreach to deliver vital information during emergencies, such as tornadoes or pandemics like COVID-19. By providing a direct link to a comprehensive resource website, governments can ensure that those affected have easy access to the help and assistance they need, while also encouraging others to get involved through volunteering or donating. Overall, this approach helps communities

come together and recover more effectively from disasters, demonstrating the power of effective emergency communication.

Additionally, machine learning techniques can be used in microtargeting to enhance COVID-19 information behaviors within the Black American population. Microtargeting involves data analytics to identify specific subgroups of Black Americans who exhibit vaccine hesitancy or resistance, and customizing messages and communication channels to address their concerns. Machine learning algorithms can examine data from diverse sources, such as social media platforms, to detect attributes and actions of Black Americans who are hesitant or resistant towards vaccines. Natural language processing (NLP) can be used to analyze social media posts to understand their concerns, fears, and hesitations regarding the vaccine. Based on this data, public health campaigns can employ tailored messaging and communication platforms to tackle their concerns and enhance vaccination adoption (Chen, Liu, & Peng, 2019).

Another strategy includes involving local communities and their leaders in public health initiatives to augment effective dissemination of information. Collaborative filtering is a machine learning technique used to make predictions about an individual's preferences or behavior based on the preferences or behavior of similar individuals. This technique can be used in microtargeting to improve COVID-19 information behaviors among Black Americans (National Academies of Sciences, Engineering, and Medicine, 2021). Collaborative filtering models can analyze data from various sources, such as social media platforms, to identify individuals with similar preferences or behavior to those who are vaccine-hesitant or vaccine-resistant (Hacker, Auerbach, Ikeda, Philip, & Houry, 2022; Moore et al., 2022). Based on this analysis, microtargeting strategies can be designed to promote COVID-19 vaccination in the identified subgroups of Black Americans (Laurencin, 2021).

CONCLUSION
This is one of the very few studies, in Information Science, that centers Black American information practices related to the novel coronavirus. Over the last two years of the pandemic Covid-19 vaccine hesitancy has been a salient issue in the Black American community, with broad impacts and consequences; therefore, we examined relationships between coronavirus vaccine status and individuals’ coronavirus vaccine knowledge and information seeking about the coronavirus. Our results demonstrate that individuals who have received the COVID-19 vaccine exhibited greater COVID-19 vaccine-related knowledge compared to people who declined the vaccine, or were hesitant adopters. We did not observe a significant difference in the level of knowledge between those who are hesitant about the vaccine and those who declined it. Finally, we found a moderately positive correlation between COVID-19 vaccine knowledge and one’s engagement in COVID-19-related information seeking. The current study has identified a deficit in both coronavirus vaccine knowledge and information seeking among the vaccine hesitant and those who have declined the vaccine. We have proposed several narrowcasting techniques and strategies that
could be leveraged by local, state, and federal governments to help propagate critical information to increase health information knowledge and aid information seeking during crisis/emergency health events.

There are some limitations to our study. The coronavirus pandemic was a crisis event that spanned multiple years. Data for the present study was collected in June of 2021. It is possible that participants' views evolved throughout the pandemic and those fluid perspectives are not captured in this dataset. The results of this study also suggest several key directions for future research. While this study focused on Covid-19 vaccine knowledge there is an additional need for a more holistic approach that focuses on general vaccine knowledge and information seeking among Black Americans. Previous studies suggest other hesitancies with vaccine uptake, for example with influenza; as such the correlations noted in this study may also have an antecedent in the Black American community that is principally based on vaccines in general. Additionally, we see a need to examine other interactions with vaccine status. The literature suggests that some hesitancy is related to “structural inequalities, structural racism” which results in general distrust of the government and medical community alike (Dada et al., 2022). Therefore, future study will examine discrimination as a predictor of vaccine status. While some studies have measured discrimination as a variable within vaccine adoption, we have observed that none of this work emanates from an Information Science perspective. If we can better understand COVID-19 information behaviors and practices among Black Americans, we can establish better information dissemination techniques in the United States before the next pandemic.

ABSTRACT
This paper explores the social and technical perceptions of physical and digital formats as they relate to work in the recovery and reuse of scientific data, specifically historical, archival, and defunct data sources. Proprietary and obsolete formats, or formats that need significant transformation work, stand out as central challenges for scientists and data curators who are recovering reusable data from archival or legacy data sources. The challenges confronting data sharing and reuse of contemporary scientific data are already known to be myriad; formats often pose a major, compounding challenge to retrospective data curation research and practice. Based on 23 qualitative interviews with practitioners conducting data recovery and reuse, ranging from marine biologists to data librarians, we study how they understand, engage with, and utilize formats within their data curation work. This paper enumerates the formats deployed throughout the scientific data curation process and explores how practitioners creating and curating scientific data based on historical and archival materials encounter, make sense of, and utilize formats. The paper focuses on practitioner perceptions of formats around the following themes: how practitioners’ historical relationships to certain challenging formats inform their ongoing curation practices; the importance of contexts in prioritizing or ignoring formats within scientific curation work; and how formats reveal larger sociotechnical issues. The paper concludes by with practical and theoretical implications of navigating formats within the recovery and reuse of scientific data and offers suggestions for reconfiguring formats within broader data curation lifecycles.

Formats; data recovery; data reuse; scientific data; sociotechnical issues

INTRODUCTION
Research and practice in the field of scientific data curation have provided a growing body of guidance and tools for sharing and reusing recent and future scientific data, but attention to retrospective practices of curating scientific data from historical or otherwise defunct materials has been relatively limited. This leaves in limbo untold masses of potentially valuable scientific evidence—in archives, on hard drives in the basements of scientific labs, or in the papers of retired scientists, for example. Yet, these data have significant potential value to longitudinal and integrative data reuse, proven by a growing body of work on historical data reuse to support active scientific research in many fields (Choudhury, 2017; Mayernik et al., 2017; Pasquetto et al., 2017; Thomer, 2022.). The Recovering and Reusing Archival Data for Science project is investigating data recovery and reuse efforts that focus on legacy or historical data within a wide range of institutional, disciplinary, and research contexts, in particular to explore the distinctive challenges of curating data from legacy research sources as opposed to curating contemporary data. One central challenge that has emerged from interviews with scientists and curation professionals doing data recovery work lies in the material and digital formats of the data sources themselves. While contemporary curation work focuses on data that already exists as such, retrospective work often involves significant format conversions, including data extraction and transformation work. This paper explores this central challenge of data formats as a distinguishing factor between contemporary and retrospective data curation practices.

Formats provide but one context for broader practices, trends, and challenges in the recovery and reuse of archival data. Across processes of recovering, reusing, and storing data, formats—including the types and analog formats of physical media, as well as digital file formats or filetypes—serve as surrogates for data, mediate between archival preservation and curatorial usability, and often offer proprietary hindrances to reuse across physical and digital contexts (Rosenthal, 2010). Not all formats are created equally. Some are designed to offer a long-term solution for preserving information (Hodge & Anderson, 2007; Park & Oh, 2012), whereas other formats function exclusively as conduit for documentation (Pearson & Webb, 2008; Duretec & Becker, 2017). The fluidity of formats only grows when working to differentiate between digital and physical, and the migration from analog to digital surrogates and from obsolete files to new digital files (Sherring et al., 2018). Additionally, little is known about the range of places where scientific data recovery work happens and, by extension, the importance of scientific data recovery work more broadly, including the inevitable impact of formats on this work. In spite of clear calls for dealing with format obsolescence (Casey, 2015) and advocacy to make format migration work within cultural heritage institutions more visible (Lischer-Katz, 2019), the sociotechnical role of formats in data recovery and reuse remains under-examined.

86th Annual Meeting of the Association for Information Science & Technology | Oct. 27 – 31, 2023 | London, United Kingdom. Author(s) retain copyright, but ASIS&T receives an exclusive publication license.
This qualitative study utilizes findings from 23 interviews with practitioners conducting data recovery and reuse across disciplinary and organizational contexts. The overarching goal of this study is to identify common challenges for scientific data recovery and reuse across disciplines. However, one prominent theme that emerged in our findings was the wide variety of physical and digital formats with which scientists and data practitioners wrangle in the process of their recovery work. Therefore, this study focuses on a subset of our findings: on how participants discuss their perceptions of formats in the production and distribution of scientific data recovered from historical, archival, or defunct sources. First, this paper offers up an enumeration of format types across physical and digital scientific data contexts. Second, it offers insight into how practitioners identify their own curatorial expertise in relationship to formats, how practitioners contextualize the value of any given format, and what particular formats reveal about the sociotechnical issues informing institutional support of scientific data recovery and reuse.

LITERATURE REVIEW
Sociotechnical Issues in Digital Preservation/Curation
There exist well-established concerns around the dire need for proactive digital preservation and curation within cultural heritage institutions (Hedstrom, 1997). Sociotechnical concerns regarding digital preservation and curation include several issues: identifying institutional preparedness for digital preservation workflows (Ahmad & Rafiq, 2022); planning for long-term preservation of web-based content (Day, 2006); scaling institutional resources to assure digital sustainability (Montoya, 2016); and assuring that materials include enough context to explore diverse and understudied histories (Sheffield, 2016). In spite of the variety of generative outcomes associated with planning for and implementing thorough methods for digital preservation and curation, institutional and stakeholder support remain limited if present at all (Council on Library and Information Resources, 2013; Poole, 2016). In addition to the challenges associated with supporting digital preservation and curation, the perceived skills necessary for digital curation work often prove overly demanding and too technical for many practitioners (Kim et al., 2012). Further, robust preparation for the needs of digital preservation and curation remain absent from curricular pedagogy, especially within library and information graduate programs (Kim et al., 2012; Sheffer & Hunker, 2019). In response, solutions to addressing digital preservation and curation concerns range from seeking support from publishers and vendors (Smit et al., 2011; Narlock et al., 2021) to collaborative consortia work aimed at offloading costs, labor, and expertise across institutions (Trehub et al., 2019). Despite progress towards digital preservation and curation solutions, there still exists an abundance of content held in an equally abundant amount of formats. As a result, scholars have begun shifting focus to social practices of digital curation and preservation beyond institutions within what Costis Dallas (2016) identifies as the “wild frontier” of digital curation.

The continued rise of participatory digital ecosystems necessitates expansive considerations on the roles and responsibilities of digital preservation and curation. These shifts in participation require institutions and practitioners to reimagine how they understand their work and how we train individuals to identify, enact, and prioritize digital curation work (Becker, 2018). One response to this increased social responsibility includes open data and citizen data work, especially within the sciences (Molloy, 2011; Purdham, 2014). As a result, the obligations associated with allowing for open participation in data curation raise questions around usability and barriers to access which, as will be discussed, surface questions around uniform, long term accessible file formats (Juell-Skielse et al., 2014). In addition to making curation work more open and collaborative, shifts in focus include valuing and prioritizing community-based data curation and understanding legitimate community choices to keep their own data outside of institutional settings (Curry et al., 2010; Dallas, 2016; Gupta et al., 2023). Additionally, awareness of uneven institutional support and infrastructures for digital curation paired with many different community needs for data has resulted in a shift towards valuing both professional and amateur labor in the digital preservation and curation processes across physical and born-digital contexts (Cox, 2009; O’Neil, 2017). Importantly, the shifts towards amateur and community digital curation work opens up venues that provide methods for both institutional, content building vis-a-vis something like the National Archives and Records Administration's Citizen Archivist project (Liu, 2021).

Formats and Data Curation
The rise in digital librarianship and the responsibilities by libraries to curate both digitized and born-digital data increased concerns about both format and technological obsolescence issues and the perceived role of information institutions and their staff members (Yadav, 2016). For academic libraries format migration represents a sliver of a broader digital curation environment, which already suffers from a lack of technical expertise and infrastructural support for relevant training on contemporary formatting needs, let alone the identifying, preserving, digitizing, and migrating obsolete formats (Rahman, 2020). Additionally, both institutional and community archives face quandaries with attending to obsolete formats, often having to offer reactive migration solutions when attending to obsolete formats, which range from transferring information from one unstable format to another rather than identifying long term preservation solutions. Further, the aforementioned lack of support both in terms of labor and resources results in archives often prioritizing rare or valuable materials at the expense of seemingly mundane or
arbitrary materials (Baker & Collins, 2017). Despite both the scientific and humanities disciplines understanding the value of data stored on obsolete formats, most institutions sorely underutilize these collections, again centering preservation and migration efforts towards more high-profile materials and collections such as rare books and manuscripts (Ordelman et al., 2019). Scholars argue that part of the reason valuable data takes precedent over the uniqueness and complexity of formats often has more to do with the expertise to use data production tools, broader access to technologies in producing information, and infrastructure to hold and treat equal all formats (Jancovic et al., 2019). As such, the obligations for format preservation and the curation of data associated with these formats became a dispersed endeavor. For example, in the case of preserving formats associated with sound recordings, work toward the restoration of older formats (i.e., a vinyl record) co-occurred with digital preservation efforts that preserved copies, alongside access copies (Canazza, 2012). Alternatively, when dealing with formats that are both physical and in need of digitization, and formats that are born-digital and in need of quality checks and reformatting (i.e., proprietary time-based media) the utilization of microservices, such as digitization vendors, takes precedence over internal solutions (Rice and Schweiker, 2019). Materials held on obsolete formats, which represent marginalized groups advocating for material repatriation can also force institutions to address migration and preservation, as occurs within Indigenous work around media sovereignty and ceding control back to tribes and their affiliates (Ginsburg, 2016). In turn, distributed networks of institutions, communities, and divergent and overlapping stakeholders result in a variety of approaches. Indeed, methods of preservation at the cross-organizational level provide useful methods for format specific endeavors, ranging from physical film heritage preservation (Antoniazzi, 2021) to preparing for ingesting and curating born-digital three-dimensional and augmented reality data (Hall et al., 2019).

Recovery and Reuse of Scientific Data

The past two decades have witnessed the rapid advancement of research and practice in scientific data curation, as the potential public value of shared research data has gained widespread recognition among a range of stakeholders, including scientists, data managers, funders, etc. The proliferation of sociotechnical infrastructures for supporting data curation and reuse—ranging from federal open access mandates to data repositories, from credentialing programs on best practices guidelines, such as the FAIR and CARE principles (Wilkinson et al. 2016; Carroll et al. 2020)—has largely focused on making interventions in the sharing and reuse of current and future scientific data. The vast accumulation of historic data records—or, still more vast body of historic artifacts, documents, specimens, and other sources of scientific evidence containing potential data—has gone largely unrecognized by the data curation field. Relatively little empirical research has addressed the recovery and reuse of scientific data from historical or otherwise defunct sources, despite the proven value of these data for supporting active and ongoing scientific research.

Historical data demonstrably support longitudinal and meta-analyses, computational modeling, and cross-disciplinary research in various domains (Wyborn et al., 2015), including ecological and climate research (e.g., Specht et al., 2018; Brunet & Jones, 2011); oceanography and earth sciences (e.g., Fallas et al., 2015; Hsu et al., 2015); archaeology (e.g., Kansa & Kansa, 2022; Faniel et al., 2013); astronomy (e.g., Borgman & Wofford, 2021); and biological sciences, health, and medicine (Wolinetz & Collins 2020; McKeown et al. 2021; Meystre et al. 2017). Scientists recover historical and otherwise defunct data to serve a broad range of research purposes. Pasqueto et al. (2017) offer distinctions among different kinds of data reuse: reuse to serve the reproducibility or replication of research outcomes; independent reuse, targeting fundamentally novel questions; and integrative reuse, which combines data from multiple sources to serve comparisons, new models, or new research questions altogether. Historical data reuse practices may exemplify any of these categories.

What is often called “data recovery” or “data rescue” is the process of enabling the reuse of data being salvaged from digital or analog sources (of many kinds) that have been compromised by any number of factors, including natural disasters, political or organizational shifts, technological decay, obsolescence, and gradual obscurity (Wyborn et al., 2015). These data may lie in handwritten tables within the papers of a retired scientist, lying unprocessed in the basement of an archive. They may live on the disappearing web pages of a governmental research agency during a shift in political administrations (as in the Data Refuge initiative — see Janz, 2018). They may have been lost to time, their traces only visible in published, visualized charts and graphs that reference source numbers that have evaporated. They may be buried in inaccessible file formats on a defunct harddrive—or, in contrast, they might be eminently accessible from a technical perspective but unusable due to uncertainty around intellectual property constraints.

Data curation as a field is concerned with making and keeping data accessible for lifecycles of use and reuse over time, including practices and processes such as data sharing, data citation and evaluation, documentation, description, and preservation (Cragin et al., 2010; Higgins 2008; Vearncombe et al. 2017). Within this broader field, data recovery emphasizes aspects of curation applied to data no longer in use, or data that are not usable: data that are at imminent risk of being lost, data that are not usable as such, and data from the past. In many cases, data being
subject to data recovery were never shared as such, or never intended for broad distribution or open-ended reuse, and therefore lacking documentation, computational amenability, and critical context. Mayernik et al. (2020) offer a matrix for understanding the risk factors facing research data, including losses of funding, losses of contextual knowledge, catastrophes, changes in legal status or ownership, and cybersecurity breaches. Even for data in current use, or data living in preservation repositories, the challenges facing their endurance are significant. Historical or otherwise defunct data face the same challenges, but compounded by the passage of time, separation from original creators and contexts, technological deterioration, software obsolescence, and more.

Data recovery is invariably resource-intensive. It often entails manual workflows, involving aspects of contextual research, digital-forensic work, digitization, transcription, and other significant interpretive and analytic work. Because of scale and manual labor, the most highly visible and scalable projects come from crowdsourcing (e.g., Eveleigh et al., 2014). Data recovery also often requires networks of collaboration, and relies on specialized skills that are not widely held, whether among scientists or data curators (Griffin, 2015). Moreover, the process of data recovery may raise new ethical considerations for the welfare of human subjects represented in data, or for communities whose sensitive knowledges may be represented in historical data sources. While the overwhelming focus of data curation research and practice are on contemporary and future data, there are important strands of work that have made significant headway on data recovery and data rescue, including but not limited to the Research Data Alliance Data Rescue Interest Group and the CODATA Data-at-Risk Task Group. The prior work in this vein has characterized endemic challenges to data recovery and reuse from at-risk sources, and identified opportunities for support from libraries as well as the necessity of cross-institutional collaboration (Murillo, 2014; Choudhury, 2017; Mayernik et al., 2017).

METHODS

The objective of this research was to uncover both shared and distinctive practices among data recovery practitioners in diverse institutional and research contexts. Interviews were conducted to examine case studies involving the retrieval of analog data, such as scientific formulas written by hand, and born-digital data that often existed in outdated file formats. After presenting the case studies to researchers in different agricultural subdisciplines and realizing that recovery practices were more prevalent than previously thought, the scope of the study was expanded to encompass information practices across disciplines among scientists and curators involved in data recovery work. The research presented here focuses specifically on a subset of questions related to the role of formats in their curatorial work, for a more expansive explanation of topics and findings see (Sorensen et al., 2023).

Following IRB approval, the research team engaged in 23 semi-structured interviews with practitioners across the scientific data curation landscape including: archivist, scientists, librarians, scholars, and individuals working in institutional capacities adjacent to scientific data curation such as museums, crowdsourcing endeavors, and observatories. Questions engaged participants in topics related to their experiences with scientific data curation, methods and tools for evaluating and identifying recovery worth data, procedures for recovering data, and challenges that emerged in their work. Of particular focus for this paper are questions related to the challenges and experiences working with formats in the recovery and reuse of scientific data. Interviews ran for approximately an hour and with the permission of participants were audio recorded. Upon transcription all audio recordings were deleted. A codebook was constructed emically by identifying key themes drawn from participant discussions (Guba & Lincoln, 1994). Figure 1 represents the sample code, definition for Formats, as well as a relevant quote.

| Formats | Particular formats, file formats, documentation practices or policies, metadata standards (formal or informal), or other facets of representation and description. | P01: "Yeah, we have Microsoft Excel spreadsheets. We have CSVs, we have database files, some created in Access, some created in SQL, some created in other languages…” |

Figure 1. Sample of Formats code used in analysis

In order to ensure validity, the team engaged in constant comparative coding to achieve intercoder reliability (Boeije, 2002). Emergent topics arose during coding meetings, the team examined these topics, built new codes, and reapplied additional codes accordingly. All participants were assigned a unique identifier (e.g., P01) to ensure anonymity. Additionally, when necessary, we have redacted personally identifiable information from transcripts.

FINDINGS

The findings enumerate the format types present within scientific data curation. This enumeration, while not a quantification of all potential formats, nonetheless provides insight into how scientists and the curators understand physical, digitized, and born-digital formats within the sciences, and what degrees of data structuration exist across these formats. The range of formats from which scientists and curation practitioners are conducting data recovery is striking, and necessitates in turn a wide range of transformational practices in the process of recovery. The findings
also explore the sociocultural factors that inform the navigation of formats within scientific data curation, highlighting issues surrounding the role of practitioner expertise in curation across formats, the impact of perceived informational value as a context for engaging with potentially challenging or obsolete formats in data curation work, and how practitioners’ relationships to formats within their curatorial work expose larger sociotechnical issues within recovery and reusing scientific data. Of the 23 participants, who ranged on a spectrum from scientists to data curation professionals (many of whom have joint expertise in a domain science as well as in data curation), 7 may be understood as falling closer to the “scientist” end of the spectrum, and 16 closer to the “data curator” end.

Enumerating Format Types

Broadly speaking, formats often fell into one of three categories. Formats were either physical (i.e., handwritten notes), digitized from a physical origin (i.e., scans of microfilm), or born-digital objects (i.e., 3D data models). Not all formats easily fit this distinction, of course, formats like 5 ¼” floppy discs existed as formats housing digital files, but their physicality and need for relational hardware make their relationship to the constraints of physical formats more prominent. Equally, not all formats discussed by participants neatly map onto a linear understanding of the physical format to digitized format workflow. Participants identified, for example, the presence of printed emails, webpages, and other born-digital documents as part of their navigation of formats, often raising questions about the origin and location of the born-digital originals. Participants also treated file formats as equivalent to physical formats, discussing their structure, usability, and even obsolescence in similar terms. Examples of file formats discussed ranged from basic data files (i.e., .CSV) to structured digital objects (i.e., .JPEG) as well as more complex digital objects related to scientific research, such as .DICOM files which represent a format used extensively in the production of computerized tomography (CT) scans. Perhaps most unique within the framing of formats by scientists and scientific data curators were the treating of physically occurring objects as a format type. Given that scientific disciplines such as geology and archaeology rely on natural objects, multiple participants identified rocks and fossils as a format type in their work.

Practitioners working with scientific data enumerated formats across a landscape of structured and unstructured data. Unstructured data often emerged at the creation or ingestion phase of recovery and reuse work and included physical formats (i.e., handwritten notes) as well as unstructured digital data such as digital photographs from archaeological sites. Formats discussed also included both physical and digital semi-structured data such as handwritten logbooks and .TSV files with unique tabulations and multifaceted relationship between data points. In terms of structured data, physical formats included discussions of objects like punch cards used in computer processing, whereas highly structured born-digital formats represented automated data gathering via technologies such as satellites and barometric tools. As with distinctions between physical and digital formats, the categories of unstructured, semi-structured, and structured believe how many formats rest upon particular relationships to other software, hardware, and related elements. For example, participants discussed working with Apple Hypercards and other storage devices, which relied on proprietary software only retrievable through emulation. As such, while practitioners can view data stored on these devices, it is often impossible to open the files, leaving the practitioners to do interpretive work not dissimilar to their engagements with unstructured data. While exhaustively listing each format is beyond the scope and space of this paper, the following chart provides a range of format types and structuration [Figure 2].

![Figure 2. Formats based on their degrees of structuration and proximity to being physical or born-digital](image-url)
While the metrics for the graph are arbitrary, locations represent the degree to which an object falls on two axes: on the horizontal axis, ranging from physical to inherently digital or born-digital; and, on the vertical axis, how structured unstructured a source is as a data source. By “structured,” here, we refer to the inherent logical or formal structures of data contained by or derived from the source. Where data are already explicit, and especially where they are tabular, quantitative, or computationally amenable, the data source are not explicit, or must be derived, analyzed, or created through interpretation of the source, we consider this an “unstructured” data source.

The goal of this chart is not to offer an accurate or comprehensive ontological characterization of the data sources, but rather evoke their range and variety on a couple of particularly relevant dimensions.

For most items on this chart the distinctions are clear. A specimen, for example, is both incredibly unstructured as data and wholly physical, placing it squarely on the bottom left of the chart, whereas biometric data is both incredibly structured and entirely digital placing it in the top right corner of the chart. Some objects remain more complex, such as a CD-ROM whose content may include structured data, but the requirements of additional hardware and software to open it cause it to remain unstructured and somewhere between purely physical and purely digital format. Alternatively, photographic images exist between the physical and the digital depending on their mode of production, however, all require the same degree of interpretive data making them low on the y-axis (unstructured) and somewhere near the middle of the x-axis (physical or digital). We acknowledge that some of these categorizations are debatable, but have done our best to reflect the unique ways that practitioners working in scientific data curation and reuse understand these formats.

**Embodied Knowledge and Format Expertise**

Practitioners often framed format expertise as part of an embodied knowledge that comes with the territory of scientific data curation. Participants would often evoke a specific format and connect it directly to a historical moment in scientific data curation. P01, a data curator at a national library, in acknowledging changes between contemporary born-digital file formats, noted having had to use CDs in their own prior preservation work, commenting to the interviewers that, “we also have very old database files, we, we used to just put out a CD ROM, your young folks might not remember CD ROMs.” For P01 the reality of format obsolescence is such that researchers on this project, who are likely only a generation removed in age, would be completely unaware of the role a format played in the daily storing and distributing of data. P13, an information science professor, signaled their own relationship to obsolete formats as an inherent challenge learning to prioritize good digital curation practices due to having to “reuse someone else's data [who] graduated” only to discover “that there was no documentation” and instead they were only “handed a floppy disk.” For P13 the experience led them to realize the value of migrating data whenever possible and to assure that proper documentation exists external to a format should someone need a sense of what data resides on a format relying other hardware and software to open. P04, a historian of science, exposes how embodied knowledge can actually serve as a deterrent to innovating on modernized approaches to scientific data recovery and reuse stating:

> I actually was supposed to do a project when I was an undergraduate, using punch cards, that was in 1985 or so, 86. But then I just like, there's no way of doing this. I just told the professor; I'm just going to take these cards and migrate them to something reasonable. So I took him to the computer center, back when we had computer centers. And they turned on the IBM machine and shuffled all the cards and transferred it all into a prime system. I think it was so and I'm like, I'm very happy. I did my research project using the prime version of the data that I gave him back his giant box of cards I was supposed to use along with the digital data.

For P04, their expertise ran against a culture of practice wherein a “reasonable” format misaligned with a preferred format, potentially exposing other instances in which physical formats were in need of digitization. P04, however, also admitted having to confront their own preferred format and migration preferences. Specifically, P04 recalled doing digital imaging work prior to the rise of cheaply available multi-terabyte storage and holding off for far too long before investing in the storage mechanism, assuming it to be costly and an inefficient long term solution. P14, an archivist, extends P04’s observations to another context by noting that historians of science often fail to embrace the value of physical formats since, as they suggest of historians: “we're old fashioned. We like paper. Right? So it's just hard to break out of that mold.” P14 denotes not an individual practitioner centering a format’s use, but an entire field of practice which invites speculation as to potential selection biases within scientific historiography.

Finally, an additional finding related to experiential knowledge and its impact on scientific data curation work ties to having training directly connected to format use, curation, and preservation. Recollecting again their own learning about the challenge of scientific data via the curatorial challenges of a floppy disk, P13, an information science professor, acknowledge that:

> Had I not been working in a geochemistry lab, I wouldn't have had the ability to recreate that and rerun a portion of the experiment to double check to make sure that, that the larger data set was correct. So and
that comes back to the comment from earlier, the most precious data is that data that cannot be recreated in that way. I mean, I had a very easy moment, where yeah, I was handed a floppy disk and said, "you know, use this data," but I had the ability to walk down the hall, and recreate the data.

P13’s experiences with the recreation of data being inextricably linked to a floppy disk raised within them an understanding of the value of a format role in operationalizing data reuse, causing them to prioritize and center the utility of a format with an understanding that doing so might also require changing to newer formats and file types in the future. Conversely, participants also acknowledge that their lack of embodied knowledge led them to moments of incredible confusion when tasked with migrating and digitizing a variety of formats related to scientific data recovery. In particular, P14 noted: “I had one digital imaging class where I imaged two postcards, both sides, and uploaded content into CONTENTdm and wrote metadata for it.” P14 went on to note that this lack of more enriching contexts around learning about the impact and role of formats in digital curation workflows has resulted in them having a learning curve when it comes to navigating formats in their current work. P07, an information science professor, who also teaches courses in digital curation, acknowledges the challenges of incorporating this type of format migration and digitization in classroom settings stating that “I feel like I have to eat my own dog food as a digital curation teacher. Because I teach all these best practices about file management using good names and unique identifiers. And then when you actually put it into practice, it's really hard.” P07 helps contextualize the avoidance of detailed format-based digital curation pedagogy by attending to the need for too many contextual factors to create a truly representative experience. As we will discuss in the upcoming finding, this type of contextualization proves deeply important to navigating and prioritizing certain formats in scientific data recovery and reuse.

P16, a historian of science, connects contemporary born-digital format knowledge with broader historical scientific data curation and the boons and hindrances of each paradigm in scientific data curation by reflecting:

So I think there's like a little bit of inherent mystery to some kinds of born-digital research, as a researcher, and then as somebody that does acquisitions work, it's a little bit more confusing...there’s a sort of golden age of born-digital acquisitions that we're already moving out of. And that is, like, some old person has like an old hard drive, and they could just hand it to you. And all the files are on the hard drive. And you can just copy them on.

For P16, the born-digital age of formats perpetuates and despite having had a “golden age” remains latent with challenges simply not present in a time where researchers could hand over their data on a storage device and migrate files to a digital repository. P16 also evokes the idea of “mystery” as informing some of the work from a researcher's side of scientific data recovery and reuse, an acknowledgement which explicates another of our findings concerning the value of contextual clues in navigating viable and challenging formats in digital curation work.

**Informational Values of Formats are Contextual**

Participants perceived various formats within the recovery and reuse of scientific data to prove either context-rich or context-void, which often informed how they went about prioritizing or steering clear of particular formats. Indeed, P16, whose previous discussion regarding the lack of mystery in receiving a hard drive from a research, notes that born-digital files, especially those related to proprietary software always come with contextual hindrances. P16 noted: “With digital files, maybe there's some clue that you can't access because you don't have enough information about like the context of the program, or, you know, like how the code is put together.” For P16, even though they can acknowledge that they are dealing with a digital file associated with particular programs or contexts, without being able to open the data in the required setting, they remain, at best, inclined towards inferences about what the broader dataset represents. Though P16 does not explicitly state a file format during their discussion, it likely echoes a concern raised by multiple participants around proprietary database software, which often remain inoperable as anything other than .CSV file datasets, which require considerable reconfiguring and reconstruction to rework in their original tabular form. In this case, P16 identifies a format with rich context, but proprietary barriers make the contexts of use nearly impossible to identify. P20, a metadata manager, extends P16’s observations about the distinctions between understanding the context of what a given format consists of and questions of contextual use of a given format. P20 explores how merely making available scanned PDFs of documents is not akin to providing users with the data housed on said PDF, asking “how do we get that [document] in a form people can see it, and then how do we get it in a form that people can reuse it easily.” In their discussion of reuse, P20 further clarifies that users can add layers to a PDF including a transcript, but due to resource constraints providing that additional layer from a practitioner workflow end proves untenable. P20’s example provides insight into practitioner awareness around how to extend the contexts of formats, but concedes to limited support for doing such contextualization, which as we will show in our next section reveals how formats often expose more systemic sociotechnical challenges within scientific data curation.

Participants like P17, a data librarian, identified formats that could be deeply rich contextual resources, but seem contextually challenging due to their size and scope. In discussing log books associated with cruises and naval
expeditions, P17 admits that they “don't really expect anyone to go through a 400 page cruise report to find what they need.” However, P17 also notes the potential loss of rich scholarship in this understandable avoidance as many of the logbooks include a “lot of really ad hoc, super interesting, fun stuff,” including what their organization “call[s] the ship's narratives.” P17 explained a ship’s narrative in the following way: “So every day or every few days, the chief scientist of the research crews, writes a log of what was going on that day and what they've been doing.” Latent in these explanations, P17 notes that additional scientific data, such as meteorological and oceanographic patterns, emerge within the logbooks; however, they also suggest a potential value in utilizing the massive logbooks for work related to the social practices of ship captains and their crews. In response to their own concession that the logbooks are contextually massive, P17 approaches sharing out the logbooks in smaller formats such as single document files or reports, which they then share across social media as a way to both encourage use and alleviate the contextual barrier of information overload.

When navigating the question of context within born-digital formats, multiple participants argued that a combination of good preservation workflows and intentional file-level metadata could help to enrich the context of a format. In the case of P05, a data science librarian, they identify codebooks as a format whose contextual richness occurs through their having “pretty standardized documentation,” which allows for a “sort of provenance piece” regarding “how the data were collected and all of that.” For P05 the fact that codebooks often include things like the creator of the code, geographic location, and guidelines on how to interpret codes means that the format often invites use and reuse through ease of design. Alternatively, P11, an information science professor, identifies their own role in helping to assure context-richness within geo-located data observing:

“[the] data is geo-located, it's time stamped, it is validated, there's historical models to run it against it is, it is absence/presence-based so you can use it for more things because absence is implied as long as I say it's a complete checklist”

For P11, not only is the database in question richly contextualized in terms of how data were gathered, its association with a university-funded project and its crowdsourcing through scientific knowledge generation, affirm its contextual richness as authoritative. In contrast, P05 (data science librarian), argued that their engagement with codebooks, while context-rich, held no explicit a tie to co-production, which raised questions about the validity of the data generated and its potential for reuse. While both examples refer to born-digital documents, a physical equivalent emerged by way of P15, an archivist, who noted that their organization “obviously uses finding aids” to help provide context to otherwise physical formats with minimal contextual access points.

**Formats Expose Broader Sociotechnical Issues within Scientific Data Curation**

Given that format digitization and migration occur within larger ecosystems and, as suggested by the literature, often remain under-supported by institutional stakeholders, dealing with the complexities of formats for some practitioners occurred in response to the demands of broader social influences. In the case of P14 (archivist), their organization’s heightened security demands and lack of viable software led to a need for software updates, which, in turn, required that they do away with software used in emulating obsolete formats. Of the need to move away from obsolete file formats, P14 said:

*This is purely an infrastructure issue and a tracking of concerns about security, concerns about being able to track the machines. So we have this tension where we can't, you know, these obsolete software will not pass security review, in many cases, but we need the software in order to emulate the content. So we're trying to work through if we can, or the OCIO (Office of the Chief Information Officer) was trying to work through where and how they could set up a server that could do all of the many things that we needed to do...*

For P14 and their institution, grappling with format relevance occurred through broader sociotechnical demands around cybersecurity, which necessitated altering digital file standards as a safety precaution. Fortunately, P14 utilized the opportunity to create a solution for longer term preservation tied to dedicated server space. Other participants such as P15 exposed sociotechnical barriers to their ability to engage with the best practices of format migration, in response to external regulations on how and where governmental organizations could spend money. In needing to attain obsolete hardware for format digitization P14 recollected:

*I had to purchase some of the necessary programs to provide access. And that's because these programs are no longer being produced, and they're not being produced by a federally approved vendor. And the [INSTITUTION] doesn't allow us to use funds to buy things off of eBay.*

Both the physical and digital formats have caused P14 to need obsolete technologies to engage in curatorial work. However, strict mandates on utilizing outside vendors prevent them from achieving not only the easiest, but the most commonly ascribed approach to navigating format obsolescence. Like P14’s expectations to adhere to new cybersecurity protocols in their own navigation of digital formats, P15, an archivist, had to ascribe to bureaucratic
red tape which necessitated seeking out institution-approved vendor collaborations. Sociotechnical challenges emerged as a result of assumptions which understand the creation and curation of data to be a forward-looking endeavor, rather than retroactive maintenance and upkeep. P22, a science director at a research center, furthers P14’s observations by acknowledging that tape-based formats are “degrading more than glass plates do,” and “require specialized readers to manipulate” their data. Further, P22 goes on to lay out the procedural challenges of migrating content from the formats, even with a system of support in place:

And so there’s, you don’t reduce the burden of maintaining these collections just by going digital. And the existence of digital increases cost, right? You have to have a server, you have to have people to keep that up and keep it secure. And you have to refresh it as the technology changes. You can’t, you know, a bunch of CDs written 10 years ago, someone can’t read unless, again, it’s, it’s actively online in the cloud. And then what’s the next thing that happens? So there’s, there’s, there’s this moving technology. How do you maintain a digital collection? And there’s all the costs that go with maintaining the digital and the physical.

So cost is a big issue.

Where P14 noted institutional barriers to digitization and migration work in scientific data reuse, P22 interrogates broader social relationships to data production that remain concerned with advances or moments in which “technology changes” result in a curatorial “refresh,” meaning that data maintained in obsolete formats become cost-sinking initiatives and lead to decisions to simply “throw away” data with the hopes that an observation is available elsewhere. P22 surfaces an unspoken sociotechnical perception of older formats wherein their data is likely available elsewhere and therefore checking becomes counterproductive, despite acknowledgements by other practitioners of hidden contextual value across older format types. Older formats in this framing are simply useless technologies, both in their physical, digital, and potentially even born-digital iterations. To borrow from P16 in what can only be described as a knowingly apocryphal statement, sociotechnical systems and their perceived relationship to formats within scientific curation lifecycles refuse to address the destruction of formats leading to situations where once practitioners “were looking for garbage bags full of papers, now [they’re] looking for garbage bags full of files.” While P16’s statement can be read as decidedly defeatist, it also provides an important site for discussion regarding experiences with formats in the recovery and reuse of scientific data inform digital curation work moving forward.

DISCUSSION

Theoretical Implications

For the participants of this study, there exists a thin line between format-based data that once existed as data as opposed to data lurking within formats related to scientific evidence (specimens, samples, artifacts, documents) that are not yet data. While this distinction should produce a clean binary between data types, the formats encountered and engaged with by participants cut across both contexts creating blurred distinctions between each. In particular, data held across formats become beholden to their immediacy of usability. Formats whose data is easily usable (i.e., retrievable) tend to take precedent in popular curatorial practices. Generally speaking, this means that a born-digital file is presumed to be the most contextually rich resource. While participants certainly acknowledged instances wherein physical preferences dismissed the need for digital surrogates, the centering of digital formats remained a preferred value. Such preferences, however, betrayed larger curatorial practices relational to format migration and sustainability when an overreliance on a particular type of digital format or standard faced proprietary-based challenges (i.e., discontinuing a database design software) or shifts in institutional thinking around data privacy (i.e., the removal of compromisable software from desktops integral to using a particular file format). In each instance the need for access to an older, albeit obsolete format with the same data, could have helped data recovery. Given the realities that many types of data, not just those associated with scientific research, exist only on outdated formats, a shift towards centering challenging formats within this work proves paramount. Formats prone to degradation such as magnetic media do require unique digitization priorities, but as our participants observed older formats can be data rich in unanticipated ways meaning that questions about how we identify sustainability in current format creation and migration can best be understood by looking towards what remains accessible and reusable on older formats. In many ways attending to obsolescence is an act of sustainability, and enacting sustainability means accounting for all possible forms of obsolescence moving forward. In an extension of a somewhat radical take on the archival mantra Lots of Copies Keep Stuff Safe (LOCKSS) allowing for some presence of outdated formats and their data to retain a presence in scientific data recovery and reuse helps to keep stuff sustainably safe.

Practical Implications

Retrospective data curation work necessitates significant transformational work—often highly labor-intensive, and demanding scientific domain expertise—on a strikingly broad range of material and digital sources of evidence. Practitioner responses to the role of formats in their daily work most clearly highlights a well-identified need for more meaningful investments in navigating formats and their contextual challenges across curation ecosystems. Whether it be antiquated rules for how to obtain obsolete hardware or older practitioners refusing to adapt to digital migration demands, the scientists and data curators in this study remain keenly aware of the need for broader
investment in changing goals. As P14 observed, a top-down policy can force immediate, albeit drastic, changes in curatorial practice, but such opportunities when properly leveraged can become sites for negotiating support for format migration, preservation, and curation training. A potential solution to addressing many of these challenges might come from policies which require public facing institutions to run audits of their format holdings. These audits can ask not only for an enumeration of what formats exist within archival and research holdings, but further contexts for what data resides on these formats. Such initiatives would result in proactive rather than reactive response to format concerns and curatorial needs. Given the well-chronicled gaps in digital curation knowledge amongst emerging information science professionals, utilizing more focused and impactful fellowships and internships aimed at identifying and addressing format-based curation needs both within and outside of the sciences. Such initiatives might help raise awareness and even alleviate issues regarding format migration and conversion within scientific data curation lifecycles.

CONCLUSION
The use of formats in the recovery and reuse of scientific data remains a vastly complex undertaking which brings to light various challenges and opportunities to extend questions about format obsolescence, data sources, and informational contexts in data recovery work. Formats function as proxies, impediments, and even linkages between sustained preservation and curatorial reusability. The fluidity of formats is further complicated by the differentiation between digital and physical formats, and the varying degrees with which the data held on those formats possess meaningful structure. Despite the importance of addressing format-based challenges such as obsolescence and accounting for format migration work within cultural heritage institutions, there remains much to understand regarding the sociotechnical role of formats in scientific data curation. Through interviews with practitioners across the scientific data recovery and reuse lifecycle, this paper provides insight into how practitioners perceive formats in relation to the production and distribution of scientific data. Though providing enumeration around formats present within scientific data curation, alongside identifying the importance of experiential knowledge, informational contexts, and sociotechnical influences of format prevalence, this paper illuminates the oft-overlooked potential of formats to expand rather than limit the possibilities of scientific data recovery and reuse. While formats will likely remain sites of instability within data curation lifecycles, the practitioners interviewed remind us that we should think twice before tossing that old hard, as it may well hold within it a data value waiting to be revived.

Characterizing and Early Predicting User Performance for Adaptive Search Path Recommendation

Wang, Ben  School of Library and Information Studies, University of Oklahoma, USA | benw@ou.edu
Liu, Jiqun  School of Library and Information Studies, University of Oklahoma, USA | jiqunliu@ou.edu

ABSTRACT
User search performance is multidimensional in nature and may be better characterized by metrics that depict users' interactions with both relevant and irrelevant results. Despite previous research on one-dimensional measures, it is still unclear how to characterize different dimensions of user performance and leverage the knowledge in developing proactive recommendations. To address this gap, we propose and empirically test a framework of search performance evaluation and build early performance prediction models to simulate proactive search path recommendations. Experimental results from four datasets of diverse types (1,482 sessions and 5,140 query segments from both controlled lab and natural settings) demonstrate that: 1) Cluster patterns characterized by cost-gain-based multifaceted metrics can effectively differentiate high-performing users from other searchers, which form the empirical basis for proactive recommendations; 2) whole-session performance can be reliably predicted at early stages of sessions (e.g., first and second queries); 3) recommendations built upon the search paths of system-identified high-performing searchers can significantly improve the search performance of struggling users. Experimental results demonstrate the potential of our approach for leveraging collective wisdom from automatically identified high-performance user groups in developing and evaluating proactive in-situ search recommendations.

User performance; Web search; search path recommendation; evaluation; proactive information retrieval

INTRODUCTION
Characterizing user search performance is crucial for modeling user behavior and providing them with customized recommendations in interactive information retrieval. The search path and strategies of users with high performance can be leveraged to enhance other users’ search results and experience under similar search tasks, cognitive states, and intents (Hassan Awadallah et al., 2014; Hendahewa & Shah, 2017; J. Liu & Shah, 2022). Users’ search performance is shaped by several factors, such as domain knowledge (i.e., users’ knowledge background and familiarity with the search task/topic), search expertise (i.e., technical skills and topic-independent search experience) (Suzuki & Yamamoto, 2021), and contextual factors (J. Liu & Shah, 2019a, 2019b). Focusing on search performance, previous research suggested that good-performing users usually have better search strategies and can effectivley accumulate knowledge and cues through interactive search activities (Mao et al., 2018; Suzuki & Yamamoto, 2021). Through leveraging collective wisdom from expert users, collaborative query recommendation can help struggling users with lower performance and fewer skills and improve their search interactions (Halvey & Jose, 2012; Morris, 2008; Morris & Horvitz, 2007).

Existing research has examined user search performance using unified behavior-based or self-report-based metrics to measure performance. The user performance is related to users’ interactions with the results (e.g., clicks, dwell time, and continue or stop searching) and their perceived search experience (e.g., search success and satisfaction) (M. Liu, Liu, Mao, Luo, Zhang, et al., 2018; Mao et al., 2016). Concerning user performance prediction, some existing studies employed the performance from previous searches and implicit feedback features (e.g., dwell time on results) to predict their search performance in current and subsequent query segments (Hendahewa & Shah, 2015; Piech et al., 2015), but many of them only considered a small set of online search behavior features collected at the whole session level (after the search session is concluded). These measures of single aspects are not capable of capturing the multidimensional nature of user performance, which may lead to incomplete and biased results in user performance evaluation (Hendahewa & Shah, 2017; Moraveji et al., 2011; Odijk et al., 2015). In addition, although various methods have been developed to support users by improving their search experience in both IR and HCI communities (Huurderman & Kamps, 2015; Smith, 2017), it is still unclear how we can leverage the knowledge about evaluating and predicting user performance at different early points of search sessions, and how effective the performance measurement is.

Research Objective
To fill the above research gaps, we developed multiple user performance measures that capture both the gain (e.g., the numbers of relevant/useful documents) and cost (e.g., the number of clicks, dwell time) aspects of users’ search interactions based on both online search behavioral features and offline relevance and usefulness labels. Differing from most of the existing measures, our metric set characterizes users’ in-situ interactions with multidimensional gain and cost. Then, based on the user performance groups identified through clustering from the measure scores, we built machine learning classifiers to predict user performance at early points of search sessions (e.g., first,
In this section, we introduced the theoretical foundations of our proposed framework and the research gap. First, as we aimed to evaluate users' search performance, we reviewed previous studies about the measures and the importance of users' performance in search tasks. Then, we planned to predict users' search performance based on their behaviors, so we reviewed methods investigating user behavioral features. Furthermore, with user performance measures and predictors, we proposed to design a method to help struggling users in search tasks, which is the interest of proactive information retrieval. Finally, we specified the research gaps in these fields and brought up our research questions.

**User Online Search Performance**

Improving user search performance and experience with search system support is fundamental in information retrieval (Huurdeman & Kamps, 2015). User search performance is shaped by many factors, such as domain knowledge (M. Liu, Liu, Mao, Luo, Zhang, et al., 2018; Suzuki & Yamamoto, 2021), task complexity (P. Liu & Li, 2012; Payne, 1976; Willett et al., 2014), search skills, and search experience (Bailey, 2017; Wildemuth, 2004). Users from various domains with different levels of search experience will perform differently on specific search tasks (M. Liu, Liu, Mao, Luo, Zhang, et al., 2018; Moraveji et al., 2011; Suzuki & Yamamoto, 2021). Evaluating user search performance usually involves assessing their success in the search task, which can be done through self-reports or analyzing user responses (M. Liu, Liu, Mao, Luo, Zhang, et al., 2018; Odijk et al., 2015). However, collecting user-generated annotations can be costly, so there is a need for metrics that evaluate user performance with limited user annotations and implicit feedback. Recent research has focused on online metrics for information retrieval systems that combine offline metrics (e.g., relevance-based metrics) and online user behaviors (F. Zhang et al., 2020). These metrics can reflect user search behaviors and performance from multidimensional aspects (Hendahewa & Shah, 2017; J. Liu & Yu, 2021). According to information foraging theory, user interaction signals are associated with search outcomes in varying ways, and this outcome-behavioral relationship is affected by the goal of information gain, tolerance of cost, or the rate of gain and cost (Azzopardi et al., 2018). However, each online metric only evaluates search results from a single aspect, making it challenging to represent and evaluate multidimensional user search performance using user-interaction signals (Chen et al., 2017).

On the other hand, researchers have studied query performance prediction (QPP) methods to estimate query performance or system effectiveness without relevance labels (Cronen-Townsend et al., 2002; Raiber & Kurland, 2014). These methods estimate performance using textual features of the query and documents in the search results (Zendel et al., 2019). However, QPP methods neglect users' experience and are not designed for improving users' performance in web search (Zamani et al., 2018; Zhou & Croft, 2007). Therefore, how to adopt user-interaction signals to represent and evaluate the multidimensional search performance remains an open question.

**Online Search Behaviors**

User search performance is closely associated with their online search behaviors (F. Liu, 2016). With the development of the modern search engine, researchers have collected user interaction signals in real-time and at a large scale, aiming to develop user-oriented search supports (Bennett et al., 2011, 2012). These behavioral signals normally involve query reformulation, pagination, clicks, mouse movements, dwell time, etc. Based on information-seeking theories and user models, previous research has analyzed users' online search behaviors to personalize their interactions with search engines by inferring their implicit states (Dumais et al., 2014; Fox et al., 2005; White & Morris, 2007). Various methods have been implemented to investigate users’ search behaviors, including collecting user behavior data from user studies or large datasets of search logs and developing machine learning models to predict users’ implicit states using behavioral data (Hendahewa & Shah, 2015; Li et al., 2021). The implicit states include task difficulty, user information intention, information need, satisfaction, etc (Arguello, 2014; J. Liu et al., 2020; F. Zhang et al., 2020). In addition, researchers also found distinguishable patterns in online search behaviors...
between users with high search performance and those with low performance (Lazonder et al., 2000; Mao et al., 2018; Suzuki & Yamamoto, 2021; Yu et al., 2018). Furthermore, users exhibit different behavioral patterns in different states of the search task. Based on these patterns, researchers have proposed to develop adaptive models to predict user states at different moments during sessions (Arguello, 2014; J. Liu & Yu, 2021). Practically, predicting users’ implicit states such as domain knowledge could enable search systems to support users proactively in achieving a better search experience (X. Zhang et al., 2015).

Proactive Information Retrieval

Proactive information retrieval aims to improve users’ search experience and performance from the traditional search system with a reactive nature (Bhatia et al., 2016). Users with different levels of search experience, domain knowledge, or information literacy can all get support from proactive search systems (Huurdeman & Kamp, 2015; Savenkov & Agichtein, 2014; Smith, 2017). Query recommendation is a popular proactive information retrieval method that has demonstrated usefulness for users engaging in various types of tasks (Hanauer et al., 2017; Hendahewa & Shah, 2015, 2017; Moayedikia et al., 2019; Zahera et al., 2013). High-quality, collaboratively recommended queries created by expert users can provide guidance to users and improve their search performance (Harvey et al., 2015; Morris, 2008; Morris & Horvitz, 2007; Savenkov & Agichtein, 2014; Smith, 2017). Another aspect of assisting users is helping the search system adapt to users’ states according to their behaviors (J. Liu & Yu, 2021; Rha et al., 2016). The adaptive search system can improve search results during the dynamic interaction between users and the search engine (Luo et al., 2014). When users are struggling with search tasks, these proactive methods are supposed to assist users in accomplishing tasks with positive interventions. Therefore, by accurately estimating users’ search performance, queries from high-performance users can be collected to help users with low performance of the search task in the proactive information system.

RESEARCH QUESTIONS

Although there is much research about adaptive search systems supporting users, most of them focus on a single facet of user behaviors or the system performance based on traditional relevance-based offline metrics. Few studies investigate user performance directly to develop adaptive search systems because of lacking appropriate evaluation metrics for multidimensional user performance. This research aimed to evaluate user performance with the combination of various online metrics in terms of gain and cost. Then, we investigated the feasibility of early prediction and intervention to support users after evaluating their performance. Therefore, we aimed to address these research questions:

RQ1: From what aspects can we measure user search performance using online-offline combined search measures?

RQ2: How early can we predict user search performance in an interactive search session?

RQ3: To what extent can we improve a user’s search performance with search paths extracted from the search sessions of other users engaging in the same search task?

DATA AND METHODS

This section introduces the methodology we employed to create multidimensional user performance measures and evaluate early-prediction-based search path recommendations. First, we introduced the datasets used in this study and what features and performance measures we can extract from these datasets. Then, we described our framework of search performance evaluation, how to investigate the predictability and effectiveness of the performance evaluation by early prediction with behavioral features, and query segment recommendation simulation.

Datasets

As this research aims to support users with queries extracted from high-performance users’ search sessions, some features we need include information on users’ behaviors and assessments of the results to evaluate user performance. Therefore, we used the KDD19 dataset (M. Liu et al., 2019), SIGIR16 dataset (Mao et al., 2016), SearchSuccess dataset (M. Liu, Liu, Mao, Luo, Zhang, et al., 2018), and the TREC session track 14 dataset (https://trec.nist.gov/data/session2014.html) in this research. We listed the basic information about these datasets in Table 1. These datasets contain topic/task-based search logs where users could have multiple queries in one session, and their search behaviors were collected, including query reformulation, clicks, paginations, and timestamps. The KDD19 dataset also collected additional user behaviors such as mouse movements, scroll, and hover activities.

Table 1. Characteristics of Datasets.
For the annotations, the KDD and SIGIR16 datasets collected relevance for all documents and usefulness for clicked documents. The SearchSuccess dataset collected relevance and usefulness only for clicked documents. The relevance and usefulness annotations are different assessments reflecting two aspects of the documents (Mao et al., 2016). The relevance is assessed by external experts based on the topical relation between the information and the search task. The relevance score is from 0 “not relevant” to 3 “very relevant”. The usefulness is annotated by the users about their perceived usefulness of the result, and the score is from 1 “not useful at all” to 4 “very useful. Users’ satisfaction feedback on a session was also collected in these three datasets, on a scale of 5, from 1 “low satisfaction” to 5 “high satisfaction”. The TREC14 dataset contains only relevance annotations on a scale of 6, including -2 “spam” and 0 to 4 (from “not relevant” to “navigational”). The user interactions in the TREC14 dataset are quite sparse compared to the other three datasets, and only 641 out of 1257 sessions contain at least one click. We filtered out sessions with zero clicks from the TREC14 datasets as we intended to evaluate action-based performance in search sessions. In addition, the KDD19, SIGIR16, and SearchSuccess datasets were collected in a lab-controlled environment for user studies with college students as participants, and the queries are in Chinese. The TREC14 dataset containing English queries was collected for a different purpose as an information retrieval evaluation instead of the user study. The search tasks are general topics in the KDD19, SIGIR16, and TREC14 datasets, while the SearchSuccess dataset contains search tasks in different domains.

**Search performance evaluation, early prediction, and recommendation simulation**

Figure 1 illustrates the study process, which involves evaluating user search performance, predicting the performance levels, and simulating collaborative query recommendations. We first designed a set of online-offline combined measures and used a clustering analysis on these measures to group users by their performance levels. We then investigated the predictability of performance levels through early prediction by search behaviors and compared the queries between high- and low-performance groups as the simulated collaborative query segment recommendation.

**Figure 1. The overall framework of performance evaluation, early prediction, and recommendation simulation.**

**Search performance measures and evaluation**

In the **Search performance evaluation** step in Figure 1, we extracted features of users’ behaviors and document annotations from the search session and created online-offline combined measures based on those features and annotations. The online measures were calculated from users’ online search behaviors, and the offline measures were calculated based on the annotations of the documents on the search engine result pages (SERPs), such as relevance, usefulness, and discounted cumulative gain (DCG) scores (Dupret, 2011). We combined the online and offline measures to evaluate users’ behaviors and grouped the measures into gain- and cost-based measures, which are listed in Table 2. We selected these measures from a large set and removed highly correlated measures. These measures are the sum values at the session level and can represent different aspects of users’ gain and cost in completing the search task. We did not involve dwell time on relevant or useful documents as it was unclear when a user had high efficiency in locating required information in the document or spent a long time exploiting abundant relevant information.

| Table 2. Online-offline combined performance measures grouped by gain and cost. |
After obtaining the online-offline combined measures for each session, we conducted a correlation analysis to investigate the relationships between these measures and users’ satisfaction state. We used Spearman’s rank as the statistical test method since satisfaction is ordinal data. We incorporated measures previously examined (e.g., DCGrel and DCGuse) regarding the correlation with user satisfaction at the query level (Chen et al., 2017; Mao et al., 2016) with other measures we created in this research. We performed the analysis on the KDD19, SIGIR16, and SearchSuccess datasets since the TREC14 dataset does not contain user satisfaction labels. In addition, we utilized the Benjamini–Hochberg method to control the false discovery rate for multiple comparisons (Thissen et al., 2002).

To evaluate users’ performance based on measures with multiple aspects of gain and cost, we used K-means clustering analysis on these measures to group search sessions with similar performance characteristics. We normalized all measures in Table 2 and involved them in the clustering analysis. The number of clusters is determined by the elbow method. Then, we visualized the cluster distributions on projections of the gain-cost measure pairs and investigated the patterns for each cluster to identify clusters with characteristics of high performance. We expected to find clusters of sessions with high gain and low cost, characterizing users in these clusters as high performance, and users in clusters of sessions with high cost or low gain as low performance.

**Predicting user performance in the session**

After investigating the characteristics of these clusters and identifying high-performance patterns, we developed a prediction model to classify search sessions as either high-performance or not by predictor features of users’ search behaviors. The performance level is a binary label assigned to sessions based on whether they are in the high-performance cluster. The predictor features include behavioral features from the datasets, and the descriptions are listed in Table 3. We also normalized the data and handled imbalanced data. We developed and compared different classification models, including logistic regression, random forest classifiers, and feedforward neural networks. The classification models were chosen for this study because they are commonly used in machine learning to classify data into different categories. Logistic regression is a simple and widely used model that is effective when the outcome is binary. Random forest classifiers are ensemble learning models that combine multiple decision trees to increase accuracy and reduce overfitting. Feedforward neural networks are powerful models that can learn complex relationships between features and outcomes. The model was evaluated by accuracy, precision, recall, and f1 score.

Table 3. Behavioral features.

After comparing the performances of three model settings on prediction with features in the whole session, we chose the best model setting to investigate the early prediction problem by evaluating the model performance at different query orders in the search sessions. From different query orders, the behavioral features are aggregated by the average values. For example, if predicting at the second query, we use average values of behaviors in the first two queries as shown in Figure 1. The models trained with data at different query orders were evaluated to determine how early the researchers could predict user search performance in a session.

**Query recommendation simulation**

With search performance measures and prediction models, the third step of our research is to verify the effectiveness of our performance evaluation and prediction framework. We investigated how high-performance users differ from others in terms of their search behavior, specifically in terms of their query segments, including the query, retrieved
documents, and click interactions on the documents (Hendahewa & Shah, 2017). As users with high search performance can issue better queries that retrieve more relevant or useful documents on SERPs (Moraveji et al., 2011; Odijk et al., 2015; Salmerón et al., 2005), we wanted to determine whether users with estimated high performance in our study also have better query segments than users with low predicted performance.

To answer RQ3, we simulated a query segment recommendation process to compare the query results between the high-performance sessions and other sessions, shown in the Collaborative query recommendation simulation part in Figure 1. The recommendation simulation is developed on two facets: first, given the performance labels, evaluating the recommended query segments, and second, given behavioral features, predicting the performance levels and evaluating the recommended query segments. By comparing the results between these two facets and the original query segments, we can validate the effectiveness of our performance evaluation process in differentiating high- and low-performance users and the feasibility of predicting the performance level with behavior features. We used two methods for recommendation: (1) recommending the entire search path based on the similarity of the i-th query and (2) recommending query segments based on each query’s intention. The first method simulates the recommendation of the whole search path from the high-performance group (Hendahewa & Shah, 2017), and the second method designed in this study simulates the adaptive recommendation which is relevant to user search intention and needs.

The query intention was categorized based on the typology of query reformulation types proposed in Rha et al. (2016) and some query intentions are listed in Table 4. In this study, we simplified the query intentions into four main types based on query reformulation types, including generalization, specialization, word substitution, and new, because of the limited data size for specific search tasks. Based on the characteristics of these query intentions, we classified the user’s original query intention by comparing the current query and the previous one query. For the adaptive query recommendation simulation, we first collected queries from high-performance queries with the same intention for the recommendation list. Within the recommendation list, we selected the top five queries by similarity with the current query. We evaluated recommended query segments and used the original sessions as the baseline.

The evaluation metrics include discounted cumulative gain (DCG) (Dupret, 2011), normalized discounted cumulative gain (nDCG) (Wang et al., 2013), and mean reciprocal rank (mRR) (Chapelle et al., 2009) on both relevance-based scores and usefulness-based scores.

RESULTS
RQ1: User performance measures and evaluation
After creating the performance measures for each dataset, we did a correlation analysis to investigate the relationships between the performance measures and users’ search satisfaction. Table 5 presents Spearman’s ranks of measures with users’ satisfaction. The cost-based measures, such as ClicksIrrel and MissRel, have negative correlations with satisfaction in these three datasets. This negative impact is brought by users’ costs during the search process (Mao et al., 2016). However, some gain-based measures also showed negative correlations with users’ satisfaction, such as DCGRel and ClicksRel, which may be related to users’ efforts to reach a high gain level. In general, cost-based measures had more significant impacts than gain-based measures in the KDD19 and SIGIR16 datasets, which share similar measures of significant relationships due to the same search tasks and similar data collection procedures (M. Liu, Liu, Mao, Luo, & Ma, 2018). However, for the SearchSuccess dataset, only two cost-based measures significantly related to satisfaction, and ClicksUse was the only measure showing a positive correlation among the three datasets. The relationships between the measures and users’ satisfaction indicate the tradeoff effects in the gain and cost measures. Moreover, the differences between the SearchSuccess dataset and the other two datasets suggest that some performance measures have different impacts on users’ satisfaction in datasets with different experimental settings, and it is critical to analyze these performance measures from multiple aspects.

To investigate user performance in search tasks with multiple cost-gain-based measures, we employed clustering analysis on those measures and grouped the search sessions. The number of clusters was set at five, determined by the Elbow method based on a tradeoff criterion between the cluster number and the mean sum of squared distances to centers (Kodinariya & Makwana, 2013). As the clustering analysis is based on multiple measures, it is difficult to
examine the session distributions on all measures directly. Therefore, we visualized cluster distributions on several projections of individual gain-cost measure pairs (e.g., ClicksRel-ClicksIrrel, ClicksUse-ClicksNonuse). Figure 2 shows examples of the cluster distributions on the projections of gain-cost pairs for the KDD19 and the TREC14 datasets. For the SIGIR16 dataset and the SearchSuccess dataset, the cluster patterns and distributions are similar to those in the KDD19 dataset. We further summarized the cluster patterns in Table 6. In general, the five clusters captured in clustering analysis can be aggregated into two groups based on the gain level, including high gain and low to medium gain. Within each group, the clusters in the four datasets share similar patterns. For example, all four datasets have one or two clusters in the high gain group, such as cluster 0 in Figure 2. These high-gain groups are based on both relevance and usefulness measures for the datasets with usefulness annotations. However, the sessions in this cluster are not distinguishable by cost-based measures, and the cost is variously distributed. For the low to median gain group, some clusters also contain a few sessions with higher gain on specific measures, such as several sessions in cluster 1 in Figure 2(a) and cluster 3 in Figure 2(c).

Table 6. Cluster ID and session numbers by the level of gain.

Figure 2. Examples of cluster distributions on projections of gain-cost measure pairs for the KDD19 and the TREC14 datasets: the clusters are mainly separated by the gain level, but there are fewer distinguishable patterns among clusters in terms of the cost.

Overall, the search sessions are consistently clustered by the variance of gain-based measures in all four datasets, but there are fewer distinguishable patterns among clusters in terms of cost. Although the pattern of low cost and high gain is not captured in the clustering analysis exactly, sessions with more queries and relevant or useful documents for the related task as the overall gain level can be considered high-performance sessions. Those high-performance sessions outperform other sessions not on single metrics but on a combination of multiple metrics (e.g., relevance-based, usefulness-based, and behavioral metrics). Although the high cost of these sessions seems to correlate with the high gain, a large number of query segments from the high-performance session cluster are still useful for collaborative query recommendation to support other users in low or medium-gain clusters, especially those with
lower estimated performance and who struggle searching for useful information. Therefore, we aggregated and labeled the clusters in the high-gain group as high-performance clusters and others in the group of low to median gain as low-performance clusters. This classification serves as the basis for following early prediction of user performance and the simulation of search recommendations.

**RQ2: Early prediction of user performance**

From the last step, we obtained high-performance clusters with sessions of more queries and more relevant documents and differentiated them from low-performance ones. Built upon RQ1, we developed classification models to identify high-performance sessions with user behavioral features to classify all sessions into two categories based on the cluster labels. Based on the preliminary results of the performance with different model settings, we chose feedforward neural networks as the model with the best performance. Figure 3 presents the prediction performance of neural network models at different query sequences in a session (e.g., initial query, 2nd query, 3rd query, etc.) for the four datasets. For the KDD19, SearchSuccess, and SIGIR16 datasets, the model performances gradually increased as search sessions proceeded with the increasing query order shown in Figures 3(a), 3(b), and 3(c). The elbow of the prediction point was observed at the third or fourth query, and the performance became relatively stable when the query number reached seven. This trend reflected the positive correlation between the query number and model performance for the whole session. However, during the initial few queries, the model’s ability to accurately identify the performance group that a session belonged to was limited, as the variations in user behaviors were insufficient. As the session progressed, the fluctuations in user behavior became more consistent with the average values of the previous three queries.

Figure 3. Model performance at different query orders.

Other than the similar trend for the three datasets, the model’s overall performance for the SearchSuccess dataset is higher than the models for the other two datasets, especially comparing the precision score. Noted that the SearchSuccess dataset contains tasks in different domain knowledge and participants from relevant domains. The higher performance indicates that user behaviors might have larger variances in the task of a specific domain than in the tasks of general topics. The TREC14 dataset showed more fluctuations with nonlinear variations and non-monotonic changes in the model’s performance. These fluctuations may be caused by the different characteristics of the dataset and less consistent variance in the fewer behavioral features. There were some false-positive predictions among models, indicating that some low-performance sessions were misclassified.

In general, the developed classification models can effectively identify high-performance search sessions based on user behavioral features. The results showed that the model performance gradually increased along with the query order for most datasets, except for the TREC14 dataset. However, false-positive predictions were common among the models, highlighting the need for further evaluation of the model’s performance. Therefore, we need to investigate if the sessions of predicted high performance are actually better than others with lower estimated performance for the same task. This part is explained in the next subsection.

**RQ3: Simulated search recommendation**

In the final stage of our research, we aimed to apply the knowledge gained from RQ1 and RQ2 to support users by employing early prediction models to simulate and evaluate search path recommendations. Our evaluation metrics included relevance-based and usefulness-based DCG, nDCG, and mRR. We compared the performance of the original query segments (Original) with that of two query recommendation methods: switching the query segments for the entire search path (Entire) and adapting each query segment based on the query intention (Adaptive). Furthermore, we compared the results based on the high-performance target labels without prediction (the Actual performance labels) with those based on early prediction results (Pred@k: with the labels predicted at the k-th query). Table 7 presents the query segment recommendation results for each dataset. The values are average scores of recommended or original query segments. Higher values for DCG or nDCG and lower values for mRR indicate better performance. In general, the results show that the recommended query segments demonstrated significant improvements over the original query segments in almost all relevance-based and usefulness-based scores with actual labels and predicted labels across four datasets. With the actual performance label, one or both recommendation methods can perform better than the original query segments. With the predicted label, some
metric scores showed greater improvements than those with actual labels. Additionally, in contrast to the increasing performance of the prediction model with more queries in RQ2, the query recommendation performance of the prediction point at the first query is similar to that of the prediction point at the second or third query. This finding highlights the potential of early prediction in supporting users.

Table 7. Results of query recommendation simulation.

Additionally, we compared the usefulness-based and relevance-based scores of the recommended query segments and found that while the usefulness-based scores showed improvements, the relevance-based scores did not always do, as measured by nDCG and mRR in the SIGIR16 dataset. This discrepancy may be due to differences in the assessment processes used for the two types of scores. Users assess the usefulness of the documents they click on, and those with more clicks tend to have more usefulness assessments, resulting in higher usefulness-based scores and groups of high-performance sessions. Furthermore, in the SearchSuccess dataset, the relevance assessments were only for clicked documents, and this assessment may lead to bias in evaluating the query performance (e.g., users in high-performance groups might find more documents at lower ranks), affecting the improvements in relevance-based scores, particularly mRR, of recommended query segments.

**DISCUSSION AND CONCLUSION**

**Research Findings**

With the theoretical foundations of user online search performance, online search behaviors, and proactive information retrieval, we proposed a framework for evaluating users’ search performance, early predicting their performance with behavioral features, and assisting low-performance users with query segment recommendations. For the three RQs, we have the following answers:

**RQ1: Characterizing multidimensional search performance.** We combined users’ online behaviors with relevance- and usefulness-based offline metrics to measure users’ search behaviors by gain and cost. Previous research usually focused on one aspect of performance in search tasks, such as effective results, efficient interactions, knowledge increment, and increases in search skills and domain knowledge (Moraveji et al., 2011; Savenkov & Agichtein, 2014; Wildemuth, 2004). Our approach is unique in that we use various features and assessments to measure the total gain and effort to complete the task, providing a more comprehensive understanding of user performance. When analyzing the clustering results, we found that users in the high-gain group had high levels of relevance and usefulness assessments with more interactions in the session, including more queries and clicks for more relevant or useful documents. It indicates that their performance requires high effort, search skills, and experience. However, we also found that most measures negatively impact users’ satisfaction. This finding suggests that search systems
should focus on both search success and user satisfaction by considering multiple performance measures and optimizing the search results with minimum search effort (M. Liu, Liu, Mao, Luo, Zhang, et al., 2018).

On the other hand, we observed that some low-cost users in the medium gain group, especially the low-cost outliers, might also be considered high-performance users. These users submitted only one query in the session but clicked on relevant or useful documents with few cost interactions. They might be familiar with the task topic and can quickly find the information they need and leave the session, demonstrating high efficiency in completing the task (Kelly & Cool, 2002; Odijk et al., 2015; Shiri & Revie, 2003). However, we caution that their search strategies might not be appropriate for other users with less knowledge of the task topics.

**RQ2: Model performances at different query orders.** We evaluated models built with varying methods in early predicting search performance. The results indicate that the query order influences model performance in the KDD19, SearchSuccess, and SIGIR16 datasets. Based on the performance trend, it suggests predicting the third or fourth query might be the optimal prediction point. The results indicate it is feasible to predict user performance as an implicit search state and it is possible to early predict and intervene to assist low-performance users in search sessions (J. Liu et al., 2020; J. Liu & Shah, 2022; Sarkar et al., 2020). Besides, the fluctuation of model performance after the fourth query indicates that users might leave the session before the fourth query in a real search scenario and different user behavior patterns between short and long sessions. It suggests investigating the behavioral features and applying the early prediction in the short and long sessions separately (Hassan et al., 2014).

**RQ3: Simulation of query segment recommendation.** We simulated the collaborative query recommendation by first predicting the session group at an early point and then recommending queries from high-performance sessions for the same task. As we expected the queries from users in the high-performance sessions could help users in other sessions, and the results show consistent improvements with the actual performance labels. In addition, we chose two methods of query segment recommendation and compared varying approaches to proactive information retrieval. Our proposed method might better satisfy users’ needs by recommending query segments related to their query intentions instead of recommending the entire search path as the recommender expected in previous research (Bhatia et al., 2016; Hendahewa & Shah, 2017; Sarkar et al., 2020). Overall, the improvements in the query recommendation simulation show the validity of the previous two steps in this research. The performance evaluation step can divide sessions with high performance, and the prediction step is able to predict those sessions with only behavioral features at an early point in sessions. With the last step of query recommendation, our research completes the framework of evaluating and predicting users’ search performance and assisting low-performance users.

**Limitations and Future Research**

The study has certain limitations that suggest the need for further research. Firstly, the user search performance needs to be defined across multiple dimensions beyond the sum value of each measure. The study can modify and add new factors to discuss different aspects of search performance, such as time-based gain or cost, gain/cost ratio, and increment values. The actual user performance can be set at the tradeoff point between clearance and one hundred percent completion by adjusting the weights of measures based on a better balancing of gain and cost. Secondly, the study is based on simulated research and requires further investigation of user characteristics in different performance groups to develop new performance measures and extract useful features. Future work can involve more user performance labels as evaluation baselines, direct explicit feedback on recommended search paths, and behavioral features in ablation studies to analyze feature importance. Thirdly, the study used effective but simple query segment recommendation methods, and future research can consider more advanced methods, such as AI-enabled information retrieval. User studies can be conducted to investigate how users perform given recommended query segments in real search scenarios, and the activity path in recommended query segments can also be investigated to improve re-ranking performance. Furthermore, query recommendation needs to consider users’ preferences on topically diversified results at different moments of search (J. Liu & Han, 2022).

In conclusion, this research proposed a cost-gain-based framework for evaluating users’ search performance, early predicting their performance with search behavioral signals, and supporting low-performance users by query segment recommendation. The results show the feasibility of early predicting and improving user performance in search sessions. Despite the limitations, this research contributes to understanding and characterizing multiple aspects of user performance in complex search tasks. It suggests further research to improve the multidimensional evaluation of search performance, user characteristics, and proactive information retrieval methods.

Liu, Chang  
Department of Information Management, Peking University, China | imliuc@pku.edu.cn

ABSTRACT
Research in information behavior has examined search difficulties and how people learn during searches but has not fully examined how searchers solve the difficulties on their own and gain new knowledge during this process. This study introduced the concept of insight learning during search to provide a new perspective for the studies in Search as Learning (SAL) and to optimize searchers’ experiences in a more efficient, innovative, and joyful way to combine search and learning. As a preliminary study, we conducted self-reported interviews with 30 participants to collect cases of insight learning during the search process. Based on thematic analysis of the data, we summarized the benefits of insight learning during search, described the process of how aha! occurred after impasse, and identified the antecedent, key, and consequence of insight during the search process. We aimed to help generate more insights by providing three dimensions of key factors to think about. A preliminary understanding of the insights formed in this study could contribute to further discussion about learning during the search and could help design new search tools that support effective learning.

KEYWORDS
Insight; Information Search; Information Search Process; Search Difficulty; Search as Learning

INTRODUCTION
Online search is prominent and widely used for acquiring information. From users’ perspectives, the search process typically involves expressing an information need using queries, receiving a ranked list of information items, and selecting information within the list. Besides such traditional search interaction modes, there appears to be a trend towards providing fast and organized information for searchers so as to respond to searchers’ information needs as quickly and effectively as possible, e.g., through question-answering systems, conversational systems, or artificial intelligence-generated content (such as ChatGPT). However, we may ask, is this the best way for users to acquire information? What is the most important goal for a search system nowadays? Recent research on Search as Learning (SAL) has also argued that searchers can learn through various search activities rather than just using the information system as a tool to simply find, retrieve, and collect information (Rieh et al., 2015). From this perspective, search is not just an aid to learning but learning itself. Learning is not the simple acceptance of external information but involves the active selection, understanding, and utilization of information, which is a complex information processing activity. Therefore, it is not profound enough for users to take the simple accumulation of facts as learning, and search systems need to be reconfigured to support more diverse types of learning beyond knowledge acquisition (Rieh et al., 2016). We should draw on what we have learned from learning science and other related disciplines to consider how to design search systems to support users in learning new knowledge, increasing their information literacy, and making sense of information rather than simply getting a piece of relevant information.

In this paper, we introduce the concept of insight learning into the search process to inspire the design of future learning-driven search systems and provide another perspective for SAL discussions. Imagine a child who is learning about the world for the first time and is amazed by each discovery, and another child who is typically taught by pieces of information. Both are important in understanding the way the learning process functions, but one of the biggest advantages of insight learning is its efficiency. Insight often refers to the sudden realization of the solution that pops into the mind unexpectedly, evoking an aha! moment (Durso et al., 1994; Sandkühler & Bhattacharya, 2008; Kounios & Beeman, 2014). Just like Newton and that apple and Archimedes in the bathtub, one common pattern of insight was shared: a person encountering impasse after an endeavor temporarily removes themselves from the task and then finds themselves surprised by the sudden resolution (Osuna-Mascaró & Auersperg, 2021). Other similar concepts to insights include inspiration and the aha! moment. Insight may emphasize more on the overall response, while inspiration refers to the idea itself; insight can occur without inspiration (Oleynick et al., 2014). Moreover, insight is frequently linked to a number of features, such as impasse and Aha!, that set it apart from conventional learning (Osuna-Mascaró & Auersperg, 2021). Aha! (also known as Aha! moment or Aha! experience) is the subjective experience of feeling joy and accomplishment when the solution emerged while insight or insight learning consisted of the overall process.

Nowadays, conventional information accumulation-based learning through search systems is readily available. However, it is not clear whether and how search systems could provide insights for learning or insights that facilitate increased efficiency and transfer of learning. Exploring insight in the field of information search may have several
benefits. First, insights could help searchers further deepen their thinking, broaden their minds, and even foster creativity. Second, the joy of learning new insights during the search process, as a positive emotion, could increase searchers’ perceptions of their search experience and knowledge gain dramatically. Furthermore, the impressive solutions could benefit searchers in dealing with similar difficult situations in the subsequent search process, so as to improve their learning performance and information literacy. The idea of insight learning in information science is not brand new and has been explored in several scenarios, including creating a library creative environment to better trigger insight moments (Anderson, 2011), insight during the serendipity process (Makri, 2014), and observing the eureka effect in patent prior art finding (Yang, Luo, & Wing, 2015). However, not much exploration has been done to examine insight learning during the search process yet.

This study aims to examine the benefits and process of the insight learning process during information search. Specifically, we explored the following four research questions (RQs) in this paper:

RQ1: What benefits could searchers gain through insight learning during the information search?
RQ2: When does the aha! moment usually occur during the search?
RQ3: What stages have searchers experienced during the insight learning process?
RQ4: What are the key factors that could trigger insight learning during the search?

**LITERATURE REVIEW**

Before conducting our own research, we reviewed recent studies on Search as Learning, insight learning in learning science research, and some empirical studies on search difficulties and solutions.

**Research in Search as Learning**

Insight learning is related to the field of Search as Learning in that they both stress learning during search. Research in the SAL field has investigated the learning process during search as well as the learning performance after search. Searching is often considered a learning process, and it is critical for searchers to learn both domain knowledge and search skills, e.g., how to critically seek, evaluate, and use information for various search tasks (Rieh et al., 2016).

With respect to the evaluation of learning performance, research has mainly focused on the evaluation of searchers’ learning gains in domain knowledge. For example, the learning in Moraveji and his colleagues (2011) was realized in the form of tactical search feature tips that expand user awareness of task-relevant tools and features of the search application and demonstrate search efficiency. Wilson and Wilson (2013) proposed analyzing handwritten summaries as indicators of measuring open-ended learning based on Bloom's taxonomy and evaluating the learning performance from different perspectives. Recently, Urgo and Arguello (2022) summarized methods and measures to evaluate learning performance in search-as-learning based on prior work. However, not much research has examined whether searchers gain any new search skills after they complete a search task, whether they have gained any deep understanding of domain knowledge, or whether they have found solutions to any problems.

Although Search as Learning can be challenging, various tools and features were designed to facilitate or support learning from different perspectives during search. For example, Huurdeman, Wilson, and Kamps (2016) pointed out that, without cluttering simple searches, features less commonly found in web search interfaces, when presented at the right moment, could provide value for users. Roy et al. (2021) proposed that highlighting and note-taking tools built into the search interface in a SAL environment could help learners cover more facts and subtopics. Ward & Capra (2021) proposed OrgBox as a knowledge representation tool to support complex search tasks by creating “boxes” to organize information. SearchIdea, which enabled searchers to actively interact with search results by comparison, prioritization, and rearrangement and was currently introduced by Chavula, Choi, and Rieh (2023), could also be a valuable tool to support learning during search. However, there has not been much investigation into how to provide searchers with insight during their searches. We hope our preliminary exploration of this topic can shed light on this direction.

**Insight Learning in Learning Science Research**

Insight learning has been widely discussed and implemented in learning-related science. The theory of insight learning was first proposed by one of the founders of Gestalt psychology, Wolfgang Köhler. Gestalt theory emphasizes the holistic nature of experience and behavior, and insight learning emphasizes problem solving in context, the essence of which is to engage in a completely new way (Köhler, 1969). Research in many fields has shown that insight learning has significant advantages in enhancing learning and memory (Danek et al., 2013; Danek & Wiley, 2020), which could be related to the enhancement of learning abilities, the promotion of memory migration, and the development of higher mental faculties and result in the most effective learning. It could be concluded that, different from conventional ways of learning, insight places more emphasis on the suddenness and efficiency of the solution and encourages one to be involved in the task in a brand new and creative way, hence leaving a deep impression and bringing out joyful feelings.
There are several features that make insight learning unique, such as impasse and aha! (Osuna-Mascaró & Auersperg, 2021). Insights learning described in our study refers to a process. When no further progress can be made and an impasse is met (Knoblich et al., 1999), a sudden solution may come up, resulting in representation restructuring (Stuyck, Cleeremans, & Bussche, 2021), which leads to a deeper understanding of the problem and is followed by the aha! moment, a unique experience represented by positive emotions that results from uncovering the solution to the problem (Danek et al., 2014). The word impasse is most commonly used instead of difficulty to describe the struggling situation that individuals experience before the aha! moments occur. Therefore, in the current study, we will also use the word “impasse” to describe the situation when searchers experience intractable difficulties and frustrations that lead to search stagnation. Researchers have also explored several influential factors, such as different levels of mental preparation (Tian et al., 2011) and interactivity conditions (Henok, Vallée-Tourangeau, & Vallée-Tourangeau, 2020), that trigger insight learning. The release of restrictions allowed the brain to be freed from its solidified framework and was an important factor in facilitating the “pop-up” of insights (Knoblich et al., 1999).

**Search Difficulties and Solutions**

Before aha! appears during insight learning, there will generally be an impasse stage. It could be inferred naturally that search difficulties could also be experienced before aha! during information searches. Therefore, we reviewed empirical studies on search difficulty in the research field of information search. We reviewed the difficulties in complex searches as a reference for the impasse before the aha! moment appeared.

Research on task difficulty sought to unveil the reasons that create a sense of difficulty for searchers. For example, Liu, Kim, and Creel (2015) categorized frequent causes of difficulty into three dimensions: complexity, uncertain information needs, and domain-specific knowledge. It was found that common reasons leading to task difficulty were specific requirements and too much (unrelated) information based on the data collected in a controlled lab experiment. Various difficulty reasons could be linked with the different task types and different levels of topic knowledge among searchers (Liu et al., 2011).

More research efforts have been devoted to generating predictive models of task difficulty using behavioral evidence. It was found that the perceived difficulty of tasks was often closely related to more complex queries, more advanced operators, the dwell time of content pages, the dwell time of Search Engine Results Pages (SERPs), the number of content pages visited, etc. (Aula, Khan, & Guan, 2010; Liu et al., 2011). Average query interval duration, average document dwell time, and SERPs dwell time can effectively predict task difficulty (Liu, Liu, & Belkin, 2014). It was also found that using only a limited number of important behavioral variables could obtain high prediction accuracy (Liu et al., 2012). Furthermore, research that took query intervals as timestamps to generate predictive models of task difficulty demonstrated that the predictive models were effective for first-round prediction, meaning that it was possible to predict task difficulty at the very beginning of the searching process (Liu, Liu, & Belkin, 2014; Arguello, 2014).

It can be seen that when searchers encounter search difficulties, they will adjust and change their search behaviors. However, there are still unanswered questions: What are the search difficulties that users solved themselves? What are the search difficulties that users eventually give up or compromise on? What kind of experience have users had in the process of solving difficulties? In order to analyze, discover, and understand insight learning during search, we will focus on those cases where participants have tried multiple times to solve the impasse and finally accomplished and obtained insight learning.

**METHODOLOGY**

We adopted qualitative research methods to carry out this exploratory research since we had limited understanding of insight during the information search. In this section, we reported on participants, data collection, and data analysis processes.

**Participants**

Online questionnaires were distributed to recruit participants for the interview and collect cases of insight learning during the search. The questionnaires were designed by both authors and then distributed mainly to students at Peking University through Wechat (a popular social platform), the university BBS, and online recruitment group chats using an online survey platform (wjx.cn). The main target group was university students because we believed that they had more experience searching for information and were more likely to generate insight. In the questionnaire, we first explained the definition of insight learning and then encouraged participants to recall their specific experiences that contained insight learning during search recently, fill in the description of the search task, impasse, and insight, and explain how insight occurred. They were also asked to score the impasse feelings before insight, the sudden degree when insight appears, and the degree of surprise and joy after insight. Participants were also asked whether they would like to participate in the follow-up interviews. 257 questionnaires were collected. We gave preference to the participants whose cases did not overlap with others and who reported cases with stronger
feelings during the search process, as relevant feelings could be regarded as indicators of insight. Finally, a total of 30 participants engaged in the interview based on the consideration of data and theoretical saturation, reporting a total of 33 cases (P1, P6, and P7, reported 2 cases). Participants were balanced in gender (15 males and 15 females each), aged between 18 and 32. Their education level included undergraduate (13 participants), master's (12 participants), and Ph.D. (5 participants), and their disciplines included humanities, social sciences, science, engineering, arts, sports, etc. Their cases could be largely divided into four types of topics: learning (e.g., looking for research methods, P17), work (e.g., helping with the publicity work, P29), entertainment (e.g., looking for horror movies to watch, P28), and life (e.g., aiming to buy similar pants, P16), etc. The source of the task may be endogenous (e.g., preparing for the interview, P7, T7-1), assigned (e.g., assigned by the instructor, P23), or cooperative (e.g., helping a friend find information for an exam, P20).

Self-report Interview
The related research pointed out that self-report data collection methods should be included in the research on investigating the insight process (Danek et al., 2014). Therefore, the self-report interview was adopted in our study to collect data. The outline of the interviews was primarily based on the research questions of this study. Further, we conducted four pilot interviews to test the understanding of insights gained from our initial explanations and the feasibility of interview outlines. After receiving the feedback, we made minor adjustments and began the official interview. Before the interview, we first sought the informed consent of the participants. By giving appropriate guidance with illustrations of the search process and the initial concept of insights, we checked with the participants that they understood the purpose of the interview. Then the interviews began according to the interview outline. The interview outline consisted of five fixed questions: What was the search that you were searching for? What impasses did you encounter during your search? What solutions did you come up with? How did you come up with the final solution? What helped you generate insight? During the interviews, the participants were allowed to express themselves fully without interruptions, while follow-up questions (such as: Did you solve this task as you regularly do? What did insight mean to you during your search? When did insight occur during the information search? What would the procedure be like when insights occurred during the search?) were used to ensure that the interviews did not deviate from the research purpose and enrich details. The interview was conducted from January 18th to March 17th, 2022. Each interview lasted as long as the participants needed (from 45 minutes to 90 minutes). All the interviews were conducted using Tencent Meeting to record the audio. As compensation for their time and efforts, participants will receive RMB 30 for each case reported. The first author conducted the interviews and wrote down observational notes.

Thematic Analysis
The research goal of this study was to develop an initial understanding of the insights learned during the search process. Toward this end, we adopted a primarily inductive thematic analysis approach (Braun & Clarke, 2021) to identify, analyze, and report the themes emerging from participants’ narratives directly instead of trying to put them into a pre-existing coding framework. After anonymization, the interviews were transcribed verbatim. During the data analysis procedure, following the thematic analysis procedure, the collected data in the interview were summarized and transformed into coded sentences to generate themes by QSR Nvivo 12.0. The coding of themes was discussed repeatedly by both authors to better extract themes and categorize the codes. We regularly checked subjective intercoder agreement during the coding process, as past researchers have done (Magee & Simpson, 2019).

FINDINGS
This section presented our preliminary findings with respect to each of the RQs.

RQ1: What benefits do searchers gain through insight learning during the information search?
In order to identify and analyze the benefits of insight for the search, we asked searchers to compare the search process with and without insight. In summary, participants have shared three aspects of the significant gains during the search, as follows:

In terms of the search process, insights made searchers feel much happier and could improve their confidence in their own judgment, thus avoiding delays and completing the task as soon as possible, such as "with this method (the method triggered by insight), it might be more efficient. (P23)"

In terms of task completion, the appearance of insight helped searchers gain a deep impression of the search process and created a sense of satisfaction and a long-lasting memory for completing the task, thus facilitating searchers' ability to accumulate lessons learned and migrate and disseminate them to other search task solution paths. For example, P22 mentioned, "If it (a similar situation) comes up again in the future, it will definitely be very easy to solve it".
In terms of the feelings of searchers, the insight made searchers feel a sense of accomplishment and satisfaction, enhanced familiarity with the task topic, and could even satisfy their need for social interaction, as P6 addressed: "I would definitely introduce Quark (the search engine she had used to solve the task) to others about this function".

**RQ2: When does the aha! moment occur during the search?**

In order to address RQ2, we analyzed participants’ answers to the question of when aha! (the joyful feeling after breaking impasses) occurred during the information search. It is found that before the aha! occurs, searchers often experience impasses. Therefore, in this part, we first described impasses at different stages and how aha! occurred to overcome that impasse. In order to better analyze how the impasse was eventually broken, we adopted the four subprocesses summarized by Liu et al. (2021), which summarized four main stages based on the Information Seeking Model (Marchionini, 1995), namely: Understanding and Planning (including Recognize & Accept and Define Problem), Searching and Execution (including Select Source, Formulate Query, and Execute Query), Examination (corresponding to Examine Results), and Use (including Extract Information, Reflect, Iterate & Stop).

It was found that searchers have experienced different impasses at different stages, and they would identify different strategies that finally helped them solve these impasses; these strategies include clarifying, reviewing, switching, and reformulating. Before describing how they adopted different strategies, we first explain each of these four strategies in the current study. Clarifying is to redefine, understand, and possibly decompose the current task. Reviewing means reviewing the searchers’ previous experience in memory or the summarized patterns during this particular search process. By reviewing the search history, summarizing the search experience, and connecting with existing knowledge and experience, searchers can break the limits of their thinking patterns or rediscover the possible ideas that lead to new breakthroughs. Switching (which mostly represents the switching of information sources) could also be used (e.g., from a database to a search engine and vice versa) to trigger aha!. Reformulating, including generalization, specialization, word substitution, repetition, and a new query (Liu et al., 2010), refers to the reformulation of search queries and also serves as an important information search strategy. The four strategies could be used in combination.

The main impasse and the main strategies searchers came up with were described in the following subsections.

**Understanding and Planning Stage**

The main impasse reported by four participants in this stage was the inability to understand the goal of the task and express it properly to the search systems. In this stage, searchers who experienced impasse and insights were not clear about the information they needed to complete the task at the beginning of their search because they perceived the task to be complicated or exploratory. For example, two participants described their impasses as below: "If you know exactly what research method you want to use, you can do it straightforwardly, but I did not know what method I could use at that time, so I did not know what to search for at the beginning. (P3)" "Something went wrong right at the beginning: it (referring to a word) was mentioned in the recording, but I did not know what this was exactly. (P23)"

Rather than just trying different random solutions, insight learning required more comprehension. Learners aimed to understand the relationships among the pieces of the puzzle. In the Understanding and Planning stage, the impasses were mainly solved by clarifying and reviewing strategies; an example of clarifying strategy was from P3: "I later found out that I didn't really need to know what method to use, but rather I needed to identify a research question. And this website, when I clicked on it, already offered the research question. (P3)" When receiving a task and preparing to search, searchers could be frustrated due to a lack of clear ideas and plans for task completion. The search systems, especially those that present well-structured information, covered a large amount of relevant information that could create the possibility of providing new ideas or helping the searchers accumulate knowledge. Reviewing the pattern of this search process could help locate the intersection between existing knowledge and what the information system can offer, such as: "After this word appeared repeatedly, I was able to realize that this word starting with the letter B could be a personal name. Because the oral history went like this based on my past experience and the name had a specific pattern of pronunciation. (P23)"

**Searching and Execution Stage**

The main difficulty in the Search and Execution stage was formulating a proper query when lacking background knowledge and task information, as reported by four participants. For example: "I intended to describe the flower, but there was really no particularly good description. (P6, T6-1)". We found that if a searcher did not find satisfactory results in the current information source by using queries constructed on existing information, switching was found to be an effective strategy. Also, the searcher could be guided toward reviewing existing knowledge to help expand their ideas. In other words, helping the searcher review and associate the current task with existing knowledge or experience would be necessary at this stage. Switching and reviewing were combined to solve P6’s task: "My idol endorsed this search engine (referring
I later found that there was no way to find the relevant information through various channels, and then I remembered that I had joined some group chats before and found answers there, then suddenly I thought, why not try this way to see if I could find people for advice? (P20)

Evaluation impasses occur when the quality and quantity of the information are unsatisfactory. As for the evaluation impasses, if there was a problem with the quality of the information, the searcher could be guided to switching and reformulating strategies. The dilemma went like this: searchers could sometimes solve their tasks by switching strategies. However, due to the fact that searchers' task solving was strongly influenced by their preconceptions and habits, they would always choose the regular search strategy they used most. In general, relying on previous paths to solve tasks helped searchers deal with familiar tasks efficiently, but it also prevented searchers from seeing better solutions in different or unfamiliar environments. If it was a problem of information quantity, the searcher could be guided in reviewing and reformulating strategies. Search query reformulation on the searchers' own could be demanding; hence, search suggestions based on their past search history, such as reference queries or search paths when solving similar problems, could also be helpful. By offering alternative query choices like this, it could trigger searchers to continue solving the problem. When the searcher taped into and further expressed his or her new, real needs in a form that was more in line with the implicit needs, new queries could be formed and the tasks subsequently solved. Specifically, if the system presented too much information, then it could inspire the searcher to decompose the task, narrow the target, and specify. For example, P16 saw "someone on the street wearing a pair of good-looking pants". But relying only on image recognition, there was "too much" content to be recognized. After several attempts, he tried to add the "key feature" of the pants, the text "chain", to the query.

Use Stage
A total of seven searchers reported impasses during the use stage. At this stage, the searcher may not be able to extract information from the system’s feedback. Or the searcher has collected a certain amount of information, but the information is not convenient for the searcher to carry out subsequent operations. For example, "at that time, I was helping my senior apprentice analyze data using time series analysis, but we found that the data could not pass the stability test. So we were looking for ways to pass the test. But no matter how hard we looked for it, all kinds of methods could not fit in (P13)." Confronted with this during the use stage, searchers like P13 tended to rely on a clarifying strategy: "Later, I felt that I had trapped myself. So we started from the most primitive task purpose, that is, what method we can use to analyze this data instead of focusing on solving the stability problem, and then the new method came up." We could assume that the search engine itself provides a large amount of information, which may invariably enter the searcher's subconscious and facilitate the search for useful information if it were presented in a structured, organized form that was consistent with the search engine's mental model, it would be easier for the searcher to utilize the information.

RQ3: What stages have searchers experienced during the insight learning process?
This study considered insight learning during search from the perspective of the process. We identified three stages that existed during the insight learning process: impasse, incubation, and reconstruction. We have discussed impasse in the previous section and mainly discussed incubation and reconstruction in this section. Further, we located their roles during the search, namely, impasse as the antecedent, incubation as the key, and reconstruction as the consequence. Insight learning during the information search process went like this: during the search process, information accumulation and comprehension were completed, which laid the foundation for breaking impasses. There would be impasses at different stages of the information search, especially in the Examination stage. However, impasses may be broken by incubation. Finally, reconstruction was made to complete the task.

Impasse as the Antecedents
Impasse has long been recognized as an inherent aspect and hallmark of insight, and in our study, it meant when a seeker was stuck; he or she could have tried many unsuccessful trials and did not know how to move forward. The findings of RQ2 have described what impasses seekers often encounter at different stages, which will not be
elaborated again in this section, but we would like to emphasize that impasses should be regarded as the antecedent to insight learning.

**Incubation as the Key**

Why can some impasses be resolved while others are abandoned in the end? It was found that the core was in the critical stage of incubation. Incubation benefited from information accumulation and comprehension during the information search process. When the searcher interacted with the system, the information provided by the system continued to pour into the searcher's mind, some of which was understood and some of which was accumulated. The understood and accumulated information fused with the structured knowledge in the searcher's mind to trigger an insight. During the interview, when asked to reflect on their insight, P2 suggested that the main reason for the insight was "the accumulation of literature over a long period of time".

However, if searchers focused too much on the task itself, they could get stuck and, therefore, enter the incubation stage by taking a break or trying to do something else. For P2, the incubation was formed by escaping from the task and taking a meal instead: "The break helped me a lot. I felt like I had been exploring but with no results, and that was exhausting. I just thought I'd have a quick meal and then come back and continue searching, as a new beginning."

As the key to insight, incubation made searchers jump out of the box and form new angles to scrutinize, such as "After the break, I began to wonder if I was going in the wrong direction. I deeply believed that I should switch my thoughts, like maybe I should start from the collections of monographs on archaeological sites... (P2)."

**Reconstruction as the Consequence**

The emergence of aha! was certainly gratifying, but it was not the last stage of the insight learning process. Reconstruction, as a result, may occur afterwards as a following action, as P4 says, "I had to go through that previous search process again, although I was finally clear on the keywords I was searching for." Restructuring meant changing the initial solution idea to form a new one, reconstructing the previous behavior, and putting it into task resolution in a new way, thus hitting the final solution of the task. We also found that searchers immediately engaged in the process of completing the task after the insight occurred: "just bought it straight away (P16)" and "immediately followed the actions in the video (P22)", probably because searchers often experienced an extremely strong sense of meaning and achievement from the insight, and this positive emotional experience helped them to further invest their energy.

**RQ4: What are the key factors that could trigger insight learning during the search?**

This research question aimed to address why some of the participants experienced aha! during the search while others did not. During the interview, we asked the participants to recall what helped them trigger insight learning. Specifically, three key factors that trigger insight learning from the emerging codes were identified: metacognition, emotion, and information systems.

**Metacognition**

Metacognition, often discussed in the field of information search behavior nowadays, could help identify key information, make connections, and be critical for task solving. At present, there is no uniformity in metacognition strategies. When exploring insight cases, we found the following six metacognition strategies: prediction, planning, monitoring, selective focus, adjustment, and evaluation. Prediction means that the searchers who believe they have a greater possibility of completing the tasks would help them break the impasse, such as "I think this task was easy to find the solution because I think my search ability in the entertainment field was relatively good (P1,T1-2)". Planning refers to setting goals (Ward & Capra, 2021), and if the searchers have a clear understanding of the solution process from a macro and general perspective or are able to make a general plan for their own completion, it will help to trigger insights. As P4 illustrated, "I am actually a person who has a fixed plan every day; my task that day was to find relevant literature. I felt like I had to get this job done no matter what". Monitoring the feasibility of the searcher's ideas and the progress of obtaining information would also help (Ward & Capra, 2021; Crescenzi, 2016), such as "I have been exploring for such a long time and I believed I should take a break (P2)". Through monitoring, searchers may be able to rationalize their rest and thus enter the incubation period. Selective focus refers to narrowing down to the key point while leaving all other elements in the frame out of focus, such as "My search range was too large; I want to narrow it down, so I decided to recall the specific details of the pants (P16)". Adjustment represents the cognitive behavior of adjusting ideas or thinking patterns, such as "selecting the research method according to the research purpose only (P13)". Evaluation refers to the searcher's evaluation of the current achievement relative to the prospected final results during the search process (Ward & Capra, 2021), such as "Toward this end, I first analyzed why I had this problem and felt that I didn't think about this topic very clearly (P17)". By assessing the difference between the ideal goal and the current state, searchers may be able to clarify goals for the next phase.
**Emotion**

Among many variables that have been shown to predict the emergency of aha!, emotion was one of the most widely studied predictors (Orita & Hattori, 2019). Both positive and negative emotions could promote the occurrence of insights. Positive emotions could promote the efficient allocation of attentional resources (Orita & Hattori, 2019), promote the identification of cues, and broaden participants’ searches of the problem space. An example of being calm and relaxed would be: "I calmed myself down and asked myself to breathe deeply. And I decided to think about what the teacher said and tried to extract possible keywords, and it occurred to me (P25)." An example of being confident would be: "I was confident that the task would be solved successfully. Because I felt that there must be an answer, it could just be hidden, so I just had this confidence from nowhere (P29)." While negative emotions may force searchers to be more focused on the current tasks (Orita & Hattori, 2019), an example of being doubtful would be: "I thought the biggest point was that because of my doubt, I was also forced to rush. I probably based it on this skepticism, and then I started looking through the previous ones, and I found it in it (P14)." It seemed that it was the intensity of the emotional feelings that triggered the insight learning rather than whether the emotion was positive or negative.

**Information System**

It was recommended that the search systems not only simply solve searchers’ tasks or directly offer answers but also be able to trigger insights for searchers. According to the self-reported data, if the system could provide more aggregated and fine-grained search results and help visualize the searcher’s search path, it would help searchers process information faster and contribute to insight learning. First, the system should provide well-organized information that is easily absorbed by searchers, such as a collection of relevant topics. An example would be: "(This system) provided a collection of monographs, which was absolutely more convenient (P2)". Provide more fine-grained information, which could save searchers time from finding detailed information and reduce the chance of information disorientation, such as "I entered aesthetics, but the system fed me the book. The key words and title of this book had nothing to do with aesthetics, but there was a highlighted paragraph in it that mentions aesthetics, which gave me a lot of inspiration (P24)". As P1 said, when she visualized the searcher's search path, she "actually summarized experiences based on multiple times on the search and then made a summary of all the valid paths on my own, which was very energy-consuming." Therefore, if the search engine "could provide a complete path of how to search and directly summarize what these effective paths have in common", then it may largely contribute to the insight.

**DISCUSSION**

This paper explored the benefits of insight learning during search, which resulted in joyful, impressive, and meaningful learning, as well as when and how insight learning occurred, and finally summarized factors that might contribute to the generation of insight learning. In this section, we first discussed how insight learning was related to search difficulties and solutions, and then further elaborated on the power of incubation and connected insight learning during search with serendipity during information browsing. Finally, design implications and future work were proposed.

**Search Difficulties and Solutions**

People may need to seek help from search systems for difficult and complex tasks. One possible solution was to keep searchers from encountering difficulties or help them avoid them in advance. For example, Information Fostering (Shah, 2018) aimed to predict potential problems searchers may encounter and provide help (such as a document or a strategy) to overcome those problems. Another possible solution was that when the searcher encountered difficulties, instead of helping the searcher avoid or solve them, the system could offer clues to solutions, allowing the searcher to solve the difficulties on their own. Impasse was a significant contributing factor to the insight revelation as it encouraged the appearance of errors to be fixed (Dubey et al., 2021). In this study, we investigated cases where searchers overcame the search difficulties (so-called "impasses") either by themselves or through suggestions by the search systems and had impressive search experiences, so as to infer indications for the design of the search system from the second perspective. In our preliminary study, we identified four strategies that searchers found effective: clarifying, reviewing, switching, and reformulating. The strategies identified in the current study may seem familiar to some of the search experts (Bates, 1979; Aula & Kellar, 2009; Buscher et al., 2012), but they were found to be very insightful and effective for searchers in our study. The reasons for this might be that these searchers were not very familiar with these strategies or that the current search systems did not fully support or explicitly suggest these strategies. Therefore, when they came up with these strategies and found them effective, they found them very impressive. Previous studies have identified search tactics and search strategies but have not explored how to teach or guide searchers to use different strategies for different tasks or difficulties. In this study, we found that the key for searchers to experience insight learning during search was to help them jump out of their existing or limited thinking framework and try new and creative strategies when trying to solve difficulties during search or learning.
The Power of Incubation During the Information Search

Incubation is a typical phenomenon of creativity that occurs in insight learning. The power of incubation in learning-related fields may be explained by the British educator Wallas (1926), who suggested that the key step to insight was the incubation period. The incubation period was characterized by being repeatedly thought about at first (refer to the information accumulation and comprehension in our study), taking a break or releasing the focus, and then allowing previous information to enter the mind unconsciously. A final solution via restructuring old and new information could thereby be achieved.

As the key to insight learning, incubation also played a vital role during the search for information. After trying repeatedly but unsuccessfully to reach an impasse, the searcher could move on to the incubation stage. At this point, the inherent limitations were lifted, the knowledge accumulated during the search process formed an interconnected system, and individuals rearranged disorganized or useless resources in a meaningful way, but only if the searchers were able to think outside the box, using strategies such as clarifying, reviewing, switching, or reformulating.

Insight learning could not be achieved in any single attempt but was gradually acquired through various cognitive and behavioral thinking processes. Although incubation seemed to refer to relaxation and the release of constraints in its literal meaning, it also meant information accumulation and comprehension and involved efforts to think outside the box. Traditional information-seeking models have described users’ search processes. For example, the Berry Picking Model described the searching process as bit by bit based on the information gathered along the way (Bates, 1989), and Information Foraging Theory (Pirolli & Card, 1999) argued that the users’ search behaviors would adapt with the change of search context and the searchers’ cognition, and the integration of external information into existing cognitive structures may lead to the creation of new cognitive structures, or reconstructions. We also like to argue that even though insight learning seems like a sudden increase of information, the incubation stage, as a stage to step back, relax, and reorganize their acquired information, may also be important for searchers to solve problems or gain new knowledge.

Incubation has been identified as one of the creation strategies in a recent study that examined users’ information seeking behaviors and creation processes during independent topic selection as a type of creative learning task (Li, Liu, & Hansen, 2023). The definition of incubation was adopted from Hadamard (1954), which emphasized continuous work on the creative task rather than rest and relaxation. Selection and exploration in Kuhlthau’s ISP model were matched with the incubation stage. People belonging to the incubation type spent the longest time in this stage when completing creative tasks. They selected appropriate information and explored the domain to understand and analyze the task in preparation for the final creation. Nevertheless, the incubation processes in this study emphasized taking a break from pre-existing constraints through rest and relaxation. The differences may be caused by the different types of tasks investigated in the two studies. Li, Liu, and Hansen (2023) focused only on creative learning tasks, and the incubation stage might last relatively long, at least for a couple of days. While the current study only focused on one search session and problem solving, the incubation in our study emphasized the relaxation from struggling and then jumping out of the thinking frame. Particularly, it was found that the insight learning cases that stressed the incubation stage reported by our participants mainly belonged to learning or work-related tasks or were assigned by others. This could indicate that the more restrictive the tasks, the more relaxation may be needed for searchers to jump out of the current status quo. The common part of the incubation concept in both our study and that of Li, Liu, and Hansen (2023) stressed knowledge accumulation and reservation before the generation of some creative or insightful knowledge.

Connections of Insight Learning During the Search with Serendipity During the Browsing

This paper examined insight learning during the searching process, and insight has also been mentioned in serendipity-related work. For example, Makri (2014) proposed that insight learning often occurs when information is unintentionally discovered. He proposed that connection-making was established during browsing between seemingly unrelated information, leading to insights. Insight learning was achieved through the establishment of links between knowledge by extracting structural relationships for knowledge acquisition and application so that searchers had new ideas, behavioral or cognitive changes (which refers to reconstruction in our study), and felt the emotions of surprise and joy (which refers to aha! in our study) (Makri, Ravem, & Mckay, 2017). If serendipity was defined by Fine and Deegan (1996) as the unique and contingent mix of insight coupled with chance, then similarly, we could define the insight in the search process as insight coupled with purpose. In the process of serendipity, searchers’ surprising and delightful information from serendipity pushed them to places they had not been before. For insight, the surprise and joy afterwards came not only from the feeling of luck but also from the recognition and satisfaction within oneself that the solution emerged with effort.

Furthermore, with more emphasis on goal-directed or task-driven learning, insight learning during search may depend more on incubation to overcome the restriction and proactive problem solving by trying to jump out of the current mindset. How serendipity happened during browsing could also help explain how insight learning happened.
during search. It may be the case that searchers turn to aimless browsing when they encounter an impasse in completing the tasks, and then the relaxation allows searchers to enter the incubation period so that they may have a better chance of getting useful information for their tasks. The current study also indicated that in the future, the boundary between information search and information browsing may blur, and information systems should allow users to smoothly switch between searching and browsing. Such a mode may also lead to better learning performance.

**Design Implications**
This study examined the benefits of insight learning during search and investigated the reason and process of its occurrence, which could shed light on the design of future search systems to support insight learning for users. For example, the findings of RQ2 reveal that reviewing is essential to breaking the impasse. Providing retrospective functions during the search may be helpful. Based on the findings of RQ3, impasse as the antecedent is a stage at which searchers have tried multiple times but failed, so it is very important for the system to be able to detect such impasse during search and provide timely assistance to trigger insight, such as providing new search strategies or new queries to help describe the information they need. Understanding and the accumulation of information are the basis for insight. However, too much information may make searchers feel disoriented or overloaded. Hence, it is important to provide knowledge graphs or search trails for users and adjust the amount of information supplied according to searchers’ stages. Since incubation is the key to insight, search systems could facilitate relaxation or help searchers jump out of their original thinking frame by providing heterogeneous information or reducing the amount of information provided. As addressed in the RQ4, information systems could offer meta-cognition tools to help users monitor and evaluate, provide more aggregated and fine-grained search results, provide a visualized search path, and boost users’ confidence to trigger insight.

**Limitations and Future Work**
We acknowledged that this study was preliminary in its exploration of insight learning during information searches. The benefits of insight learning during search were analyzed based on the cases reported by our participants, and they could vary from individual to individual, which meant the insight for one person may not be salient or impressive for another person. However, consistent with the existing research, we regarded searchers' opinions as an important criterion for judging whether insight occurs; that is, we considered them the authorities of their own experiences (Makri, Ravem, & Mckay, 2017). It would also be useful to know how the search tasks and demographic backgrounds were related to their experiences of insight in future work. And it should be further examined to determine the effects of the dimensions of key factors that trigger insight during the search process, using user experiments to validate whether and how these factors could actually promote insights. In this study, insight learning is a process that triggers the aha! moment during the search. However, we should acknowledge that insight could also be considered an outcome and might be associated with different levels or nuances. Future work is needed to measure insight during search in detail and determine whether it could be inferred from the observation of users’ interactions or neuro-physiological signals, as well as apply it to the design of search systems or other learning systems. In the future, researchers in the field of SAL should expand the orientation of learning beyond mere knowledge accumulation to assist in the generation of more insights, creativity, etc. Search will not only be a tool to assist in the accumulation of knowledge but will also be an important choice for insight learning. How will solving difficulties in search contribute to learning? How could critical, impactful, and creative learning emerge? How do different conditions lead to different types of learning? These questions were examined briefly in our research, but they merit further investigation.

**CONCLUSION**
This preliminary study aimed to introduce the concept of insight learning during search and provide a new perspective on studies on Search as Learning. Through self-reported interviews, this study revealed the benefits of insights in terms of acquiring deep impressions, facilitating the search processes, and enhancing familiarity with the topics. Three key stages of the insight learning process were identified: impasse, incubation, and reconstruction. In addition, the study showed how impasses in different stages were resolved by clarifying, reviewing, switching, and reformulating and were guided to reconstructions. Finally, we summarized meta-cognition, emotion, and the information system as the main factors that could trigger insight learning. By profiling the source of searcher-generated solutions, i.e., exploring where the searchers’ insights come from, we meant to make a difference toward learning and help revitalize the future work of task-based information search by proposing the concept of insight and presenting a framing of insight during the search process. More discussion is bound to be needed for insight learning, but in any case, may aha! be with us!

ABSTRACT
This paper presents the history, internal processes, and finalized report of the Trans Metadata Collective (TMDC), founded to address the lack of attention paid to trans and gender diverse issues in galleries, archives, libraries, museums, and special collections (GLAMS). The TMDC, an ad-hoc group of nearly a hundred information professionals, developed best practices for the description and classification of trans and gender diverse information resources. These guidelines prioritize transparency, cultural sensitivity, correct identification, explicit descriptions of transphobia, and regular assessment of trans-related content. It examines the effects of commonly used standards and controlled vocabularies such as Resource Description and Access (RDA) and Library of Congress Subject Headings (LCSH) on trans and gender diverse people and critiques the inadequacy of these standards’ representation of those communities. The TMDC provides guidance for using existing LCSHs, recommends alternative subject vocabularies, and proposes revisions to improve representation. The paper advocates individual agency in naming and gender identification, with recommendations on contacting creators and documenting their preferences. The TMDC emphasizes the importance of minimizing potential harm and protecting privacy in metadata creation. Overall, the report aims to enhance the representation and inclusion of trans and gender diverse communities in GLAMS institutions.

INTRODUCTION
Trans and gender diverse people (here used as an umbrella phrase for people who identify as transgender, transsexual, nonbinary, genderfluid, and/or have non-Western gender identities) face unique challenges and dangers in information contexts. As a group, they often do not receive the same legal protections against discrimination as cisgender people and they are subject to significant risk of harassment, discrimination, and even violence. Within academic, informational, and professional contexts, many experience a form of personal trauma connected to their pre-transition identities that makes them especially vulnerable (Tanenbaum et al., 2021). Trans and gender diverse people can also be misnamed or misgendered in metadata, which runs the risk of outing them and putting them at risk of harm or violence. For example, Resource Description and Access (RDA)’s requirement for recording creator gender (Billey, 2019, 2022; Billey et al., 2014, 2016; Billey & Drabinski, 2019) and the Getty Vocabularies’ collection of gender information for artist records (Harpring, 2023) represent two of many methods by which sensitive information about trans and gender diverse people can be improperly shared.

While there are many publications in Library and Information Science concerning issues faced by trans and gender diverse patrons, staff, and users of Galleries, Libraries, Archives, Museums, and Special Collections (GLAMS) (D.C. et al., 2017; Jennings, 2017; Lyttan & Laloo, 2020; Naidoo, 2018; Smith-Borne, 2019; Taylor, 2002; Wilson, 2018), little attention has been paid to issues faced in the description, cataloging, and classification of information resources related to these individuals, communities and/or their works, and even fewer have consulted members of those communities. The harm caused by information systems can be especially pernicious in cultural heritage institutions, where metadata records may persist for decades and be aggregated across multiple platforms. As metadata is often created about trans and gender diverse communities by professionals unfamiliar with these issues, work practices that appear to be neutral continue to enact harm. In order to counteract these problems, metadata best practices should be developed by those who will be affected by them, as seen in efforts like the Archives for Black Lives in Philadelphia, Protocols for Native American Archival Materials and the Chicano Studies Collection Thesaurus (Antracoli et al., 2019; Antracoli & Rawdon, 2019; CARFAC, 2021; Castillo-Speed, 1992; First Archivists Circle, 2007). To meet these challenges, the Trans Metadata Collective (TMDC) was created in 2021, with the goal of developing a series of best practices that addressed the sizable gap in information resources for trans and gender diverse materials and the communities that data is derived from. The group was formed organically over virtual, informal communication channels, eventually comprising over one hundred cataloguers, librarians, archivists, scholars, and information professionals. The variety of individuals served as a way to ensure the best practices could be instrumental for various kinds of cultural heritage institutions. This long paper discusses the

LITERATURE REVIEW

Critical Cataloging

According to Watson (2023), summarizing nearly a century of literature, critical cataloging refers to practices “deeply rooted in the history of technical work in cultural heritage institutions, librarianship, archivy, and museology—whether those practices are called alternative, radical, reformative, or critical.” (Watson, 2023) Critical cataloging literature recommends:

1. the use of multiple or alternative vocabularies or classifications, where available
2. the practice of “cultural competency” when considering historic identities, items, or groups the use of“ethical outreach” when dealing with still-living identities, items, or groups
3. “trickster” practices of “alteration,” “subversion,” or “extension” of dominant metadata principles or systems, and/or the replacement of dominant classification or cataloging on a local level
4. consultation with described subjects
5. and finally: the realization that changing words and hierarchies alone will not fix the problems or harms caused by description, cataloging, or classification (Watson, 2021).

Discussions around and about the ethical labeling of marginalized subjects in knowledge organization systems (KOS) are nearly a century old, since the publication of Dorothy Porter’s 1933 review of Oberlin’s Anti-Slavery Propaganda catalog (Porter, 1933) and the development of her Moorland-Spingarn Research Center classification system (Bledsoe, 2018; Helton, 2019; Nunes, 2018). Other approaches, like Sanford Berman’s “Prejudices and Antipathies” (Berman, 1993), Brian Deer’s classification system (Bosum & Dunne, 2017; Cherry & Mukunda, 2015; MacDonell et al., 2003; Swanson, 2015), and formation and work of the GLBT Round Table within ALA (Adler, 2012; Poole, 2020) demonstrate the wide variety of initiatives and individuals engaged in the representation of marginalized identities in LIS. They have also laid the groundwork for the breadth and depth of research and development of actionable tools used by information/cultural heritage professionals today. These items range from thesauri and terminology lists to broad policy recommendations (for comprehensive lists of current efforts, see Watson, 2023 at critcat.org, and Fox, 2023, at cataloginglab.org). Two of these resources, Archives for Black Lives and BlackLivesMatter, have pointed out that despite its flaws, LCSH may remain essential for users and researchers (Gross et al., 2015).

Concerns about trans and gender diverse metadata in GLAMS

While there are many publications in Library and Information Science concerning issues faced by trans and gender diverse patrons, staff, and users of Galleries, Libraries, Archives, Museums, and Special Collections (GLAMS) (D.C. et al., 2017; Jennings, 2017; Lyttan & Laloo, 2020; Naidoo, 2018; Smith-Borne, 2019; Taylor, 2002; Wilson, 2018), very little of it is aimed at and addresses the concerns of metadata workers at GLAMS. Scholars such as Adler (2012, 2015), Poole (2020), and others (Floegel et al., 2021) have demonstrated, queerness and queer bodies (including trans and gender diverse ones) destabilized the rules and historical understandings between catalogers and the catalogued. Resultingly, information professionals, activists and researchers have struggled with controlled vocabularies, especially ones as pervasive as the internationally-used Library of Congress Subject Headings (LCSH). While terms from controlled vocabularies broadly and LCSH specifically contain terms describing marginalized groups that are often criticized as inappropriate, misleading, or outrightly offensive (Adler & Tennis, 2013; Berman, 1993; Drabinski, 2013; Long et al., 2017; Olson, 2002; Satija & Martinez-Avila, 2017) researchers have pointed out that despite its flaws, LCSH may remain essential for users and researchers (Gross et al., 2015).

The use of authorial or creator names in metadata records is one of the fundamental principles of library and information science. Traditionally, metadata workers within GLAMS have been instructed by LIS research to include all iterations of author’s name, and authors have been directed to self-cite earlier publications. For example, Melvil Dewey spent more time and ink on the proper naming of authors in the first edition of “Classification and Subject Index for Cataloguing and Arranging the Books and Pamphlets of a Library” (Dewey, 1876) than on the subject cataloging of resources. For institutions that use MARC, creator names take precedence as the first field (1XX), and for institutions using RDA will find that a significant portion of RDA’s instructions “RDA: Resource Description and Access” (Joint Steering Committee for Development of RDA et al., 2015, Chapters 9–11) is dedicated to explaining the use of names (chapters 9-11). Finally, the two major cataloging and classification...
texts by Joudrey et. al. (2015) and Chan and Salaba (2016) each dedicate nearly a hundred pages to the processes around naming. In recent years, a number of authors—including academics, activists, and classically trained catalogers—have raised concerns around the use of names as identifiers and access points (Seeman, 2012; Shiraishi, 2019; Whittaker, 2019). Identified issues include: include the use of women’s family or married names (Kazmer, 2019; Martin, 2019), the use of colonial and anthropological nomenclature (Elzi & Crowe, 2019; Fernandez, 2018; Gilman, 2006; Kam, 1992; Rigby & Gallant, 2019), misspelled or miscopied non-Western names (including improper use of Indigenous names) (Arastoopoor & Ahmadinasab, 2019; Diao, 2015), and racist terminology (Antracoli et al., 2019; Antracoli & Rawdon, 2019).

Trans and gender diverse creators are uniquely vulnerable to discrimination and violence directly related to the disclosure of their gender identities through the names assigned to them by systems. Authors applying queer theory to cataloging have also focused on other ways information in authority records out transgender individuals. To illustrate via example, Thompson’s (2016) excellent and relevant article examines the authority records for 60 authors who self-identify as trans to ascertain if their authority records ‘out’ them as trans. By examining fields for recording name and gender, Thompson was able to identify that nearly two thirds (39/60) of the records effectively outing the authors. Only 21 of those 39 records cited the author as the source for the information about their gender identity. Thirty-four of the 39 provided more than one name for the author, either as a name set (alternate versions of a name used simultaneously) or name sequence (names that the author has used in the past but does not currently use). That so many authority records contained sensitive information that did not come from the authors themselves verified Thompson’s concern that authority records may unwittingly — and unacceptably — expose the authors in ways the authors never intended. This issue has been also explored by others who demonstrate that including gender identity in authority records is not necessary for bibliographic purposes (Billey, 2019; Billey et al., 2014, 2016; Billey & Drabinski, 2019).

ORIGINS OF THE TRANS METADATA COLLECTIVE
The initial idea for the Trans Metadata Collective project began as a conversation after a panel at the University of Victoria’s Moving Trans History Forward conference in March 2021. Within a few weeks, planning for what would become the Trans Metadata Collective began in earnest by when K.J. Rawson, Brian Watson, Beck Schaefer, Laura Horak, Magnus Berg, Clair Kronk, and Dijaz Zulida met in the summer of 2021. Recognizing the limitations of their perspectives, this planning group launched a broad call for participation on Twitter, GLAMS-relevant listservs, and elsewhere. The response to this call was overwhelming, and over a hundred GLAMS professionals expressed interest in participation. Special effort was made to recruit from the mailing lists of communities traditionally underrepresented in GLAMS.

Two large-scale meetings (called the Convening Committee) were held to discuss action plans and organize several working groups that would cover narrower themes and allow individuals to contribute based on their own expertise. These initial working groups were called Descriptive Practices, Subject Headings & Authorities, Name Authorities & Access, and Ethical Recommendations. A Slack workspace was created, and the working groups began meeting to develop individual documents. These documents took a variety of forms, including lists, bibliographies, and formal reports. On a semi-monthly basis, a representative from each working group met in a so-called Coordinating Committee in order to ensure that work was progressing and not being duplicated. As working groups finished preliminary drafts of their self-assigned work, their documents were merged into a larger document, which was edited by one or more representatives from each group. During this year-long process, individuals participated as they were able to and committees remained productive despite the challenges of COVID.

TMDC’s use of “Trans and Gender Diverse”
From the beginning, the TMDC was deliberate in its use of language (perhaps unsurprising, given that it was made up of metadata professionals). The document was meant to be a practical resource for metadata professionals, not a introductory-style ‘Trans 101.’ Members recognized that gender is a complex subject, and chose to explain their rationale behind certain decisions. This is particularly noticeable in the use of “trans and gender diverse” throughout the best practices document. Gender is not just about presentation/identity; it can also include social role and cosmological place, making conceptualizations of gender culturally specific. Translation is one way this fraughtness can be illustrated. While communication, understanding, and overlap exist between communities of people that speak different languages, gender systems may also require translation rather than direct equivalence when a specific metadata term is used. In the United States and the Western world more broadly, there is a culturally dominant understanding of gender as both binary (man vs. woman) and static (gender is based on sex assigned at birth). Other nations and peoples—both historically and in the present—have their own cosmological conceptualizations of the world and of gender where the assumptions of “binary” and “static” may not apply or may be understood very differently. Likewise, trans is a culturally and historically specific framework, which may not map exactly onto other cultural understandings of gender. Therefore the TMDC uses “gender diverse” as a stand-in umbrella term for conceptualizations of gender that fall outside of that static binary; non-Western people and
languages have had and still have their own culturally-specific gender terms, which they may use instead of or alongside the term “trans.”

This is doubly important in the context of GLAMS because of the ways that settler colonialism and colonialism abroad have influenced collecting policies and practices at Western GLAMS. Cultural heritage institutions in the West often hold at least some materials from or about Indigenous peoples; many influential white men from history were also hobbyist ethnographers. What is often called “ethnographic material” is hidden within larger collections, and the TMDC wanted to encourage professionals to consider how these guidelines apply beyond a narrow conventional understanding of “trans archives,” and to understand the ways in which trans and gender diverse resources may appear in other spaces, e.g. material on gender diversity included in an anthropological or “natural” history archive. Current society’s gender terms and/or conceptions do not necessarily map to other cultures or ways of being specific people or communities do not always view themselves as “trans” (Indigenous Two-Spirit identities, for example). While trans and gender diverse are not equivalent, there are many overlapping issues and gender diverse resources from other cultural contexts may also already be labelled with trans-specific subject terms.

**Authorship & Review**

While the TMDC’s aim was better (or even explicitly articulated) guidelines and best practices for metadata and description of trans and gender diverse resources, it aimed to be intentional in how it gave participants credit for their contributions. As the goal was to create high quality guidelines, but the collective was independently organized and did not have the funding to pay people for their expertise or labor, participation was voluntary and often occurred on top of other existing professional and personal responsibilities. While a top-down and hierarchal structure may be more efficient or clear, the TMDC attempted to create a space where people could choose to participate to the degree that they could and wanted to.

However, goals of timeliness and quality were still of importance and the work of the collective was deeply personal for the vast majority of contributors, so the group aimed to be “intentional not only about what we were making but how we were making it – in how we communicated with one another, shared labor, and made decisions” to quote from one participant. In presenting their work, the Collective aimed to represent the “how” of this process in the clearest way possible, by giving credit for in a way that fairly and accurately reflected the varying labor of contributors and the deeply collaborative and communal process of working collectively, which was often times quite different from how work occurs in other parts of member’s professional lives, in institutions that are generally more hierarchical in decision-making, division of labor, and attribution of credit. Therefore, the individuals listed in the "Authors" section of the final document were primary authors (those who wrote sections), listed alphabetically, and all other authors and reviewers ("contributors") were listed at the end of the document in whatever order they chose (mostly by peer review order). The TMDC also felt that providing a section with self-description of authors and reviewers at the end of the document also provides additional transparency on who was involved and demonstrated both our expertise and our limitations. The inclusion of reviewers was also seen as important because of the extensive dialogues that occurred during the month-long comment period that allowed the reviewers to shape the final document. This review process was seen by the collective as not style editing, but rather a formative collaborative stage in the overall guideline creation process.

Finally, according to the notes accompanying the authorship section, there were many individuals that elected or opted out of inclusion in either section due to concerns of harassment, local/national political environment, outing, and/or personal danger.

**GENERAL GUIDELINES & PRINCIPLES**

In their recommendations, the TMDC aimed for recommendations that were both concrete and actionable, not just critical or theoretical. While the collective agreed that critique is good and that theoretical frameworks are useful, its the greater goal was encouraging the adoption of consistent best practices easier by GLAMS. Furthermore, over the course of 2021 it became increasingly apparent that there was a need for a document of this type.

After discussing the possible formats of the final document, members envisioned something that would be usable across institution types and experience levels; something that could be applied in both public and academic libraries, archives, museums, and special collections at R1 institutions, independent institutions, or even local historical societies. The collective also aimed for guidelines that basic enough that they could be understood by volunteers, or new professionals, but also desired the inclusion of more detailed recommendations for readers with extensive experience and expertise in technical services, metadata, or other fields. Consequently the collective agreed on a two-part structure for its final document. The first part, entitled “General Guidelines & Principles” was high-level and conceptual, an articulation of principles or achievable goals. The second part, entitled “Domain-Specific & Technical Details” would contain granular technical guidelines to support implementation across a variety of systems. This balance was important to the Collective as their goal was not to hand down instructions from above but instead to provide support to institutions and individuals exercise their professional expertise and discretion in an
informed way. The final high-level guidelines the TMDC settled in their final document (The Trans Metadata Collective et al., 2022, p. 4):

1. making the process of metadata creation transparent, which may include making descriptive standards, rationale, and context publicly available, providing methods for user feedback, and collaborating with community members (with consent and compensation).

2. using culturally and contextually appropriate labels for trans and gender diverse communities and subjects: different cultures and communities may have terms for genders that may not translate into the typical descriptive tone or primary descriptive language. This may include Indigenous vocabulary or community terminology uncontrolled by vocabularies. Collaborate with specific communities and prioritize their terms and protocols alongside controlled vocabularies or otherwise authoritative terms.

3. correctly naming and identifying trans individuals, meaning that trans and gender diverse individuals may use different names in different points or contexts in their life and that metadata should rely on self-identification and self-description where possible, including direct consultation with individuals or communities. It is not necessary and not recommended to record information about someone’s gender identity or previous names when resources have nothing to do with gender identity.

4. being explicit about transphobia in collections, items, and metadata, meaning that metadata should identify perpetrators and victims and use active voice and subject headings to “embed responsibility.” Metadata workers and policies should aim to correct, update and remediate offensive or inaccurate language provided by other metadata creators.

5. identifying trans-related content and metadata through regular assessment and prioritizing it for remediation, meaning that institutions should plan proactively for periodic assessment and remediation, including the identification of materials related to trans and gender diverse communities and individuals, especially when they are parts of larger collections where they are not the focus. We also recommend avoiding using automation for batch replacement and caution when using externally supplied records.

**DOMAIN-SPECIFIC & TECHNICAL DETAILS**

The second major section of the document was aimed at workers with extensive experience and expertise in technical services and metadata. The collective recognized that these readers, especially those in libraries with outdated infrastructure, may face additional challenges in implementing the second and third recommendation as their work relies heavily on standards and controlled vocabularies. The most commonly used of these are RDA and the LCSH. RDA gives instructions for identifying and recording bibliographic information. LCSH provides standardized terminology for describing the subject matter of a resource.

Though limited, there are a few critiques of bibliographic descriptive systems and their impacts on trans and gender diverse people. Billey, Drabinski, and Roberto (2014) criticize the RDA instruction to record a person’s gender as reinforcing a fixed and binary conception of gender and disregarding gender self-identification. They also note that gender information is generally irrelevant to the user tasks of finding and selecting library resources. Thompson (2016) further identifies areas where gender may be recorded indirectly and points out potential problems with using former names in metadata. Thompson advocates that creators be given agency in how they are represented in library metadata. Adler (2009), Johnson (2010), Jardine (2013) and Roberto (2011) demonstrate various ways that LCSH under- and misrepresents trans people. Johnson sees a potential solution in the use of alternative vocabularies and social tagging while Adler suggests the use of folksonomies. While valuable, the recommendations in the literature are of a general nature and do not provide the granular level of instruction in reference to RDA and LCSH that catalogers need. Therefore, TMDC members drew from their own personal cataloging practices and observations, an examination of RDA and LCSH, and their associated documentation. The collective also incorporated feedback from reviewers familiar with these systems.

**Library of Congress Subject Headings (LCSH)**

At the time of TMDC’s founding, there were only four broad categories of trans identities: “Transgender people”, “Gender nonconforming people”, “Transsexuals”, and “Two-spirit people”, the latter of which is only appropriate for Indigenous resources. In turn, there were only three concepts for gender diversity: “Gender identity”, “Gender nonconformity”, and “Gender expression”. A few headings did exist centered on lived experience, including: “Gender transition”; “Transphobia”; “Gender-neutral toilet facility”; and “Social work with gender-nonconforming youth”. Though it may be obvious, the authors would like point out that eleven headings are hardly enough to encapsulate the entirety of trans life, culture, history, and more; not to mention the complete inadequacy of one heading for all of Indigenous gender identity, including those of Indigenous nations that do not have or use the concept of Two-Spirit.
While LCSH does not adequately represent trans people, the TMDC recognized that it is so entrenched in cataloging practice that it would have been impractical to recommend entirely against its use. Therefore, the report provides an overview and assessment of existing LCSHs that are relevant to transness and gender diversity. The collective identifies a significant list of harmful LCSH to avoid, aiding catalogers in avoiding harmful language. A few other subject headings require care in use since they are formulated in a way that erases trans experience, such as: “Coming out (Sexual orientation)” and “Outing (Sexual orientation).” While trans and gender-diverse people come out and are outed in ways similar to lesbian, gay, or bisexual people, unfortunately, LCSH uses headings specifically referring to sexual orientation. There is a distinction between coming out (telling people one’s true gender) and disclosing (telling people one’s trans status). To describe the latter concept, the collective recommends the use of the headings “Self-disclosure” and “Gender identity” (The Trans Metadata Collective et al., 2022, p. 12). The document details nuanced implementation for these headings and others. Following these terminology lists, the report then presents strategies to address the inadequacy of LCSH in subjects relating to gender. These recommendations include the use of alternative subject vocabularies, such as Homosaurus, which can provide more specific, nuanced, or rich terminology than what is currently available in LCSH. Utilizing terms of self-identification elsewhere in the bibliographic record are also encouraged to ensure that the record is included in search results for that term. The collective advocates proposing new LCSHs and revisions to existing LCSHs, with the document providing resources for this process.

**Resource Description and Access (RDA)**

RDA includes instructions on recording names and personal attributes, including gender. These instructions apply to bibliographic records (a record containing information about a resource, such as title, author, etc.) and name authority records (NARs). NARs are brief records that include various forms of a person’s name (including the standardized form), distinguishing biographical information, and a citation for at least one work written.

**Names**

RDA instructs that the name of an author (or other creator) appears in a bibliographic record in two forms: the form that appears on the resource and the standardized form used in the NAR. This practice can lead to not only a former name displaying publicly but a former and current name displaying together. This can out trans people, potentially putting them in danger.

The TMDC’s primary recommendation is to give authors and other creators agency over how they should be named in library metadata. To this end, the document illustrates how to contact individuals to inquire about former names and document their preferences. Acknowledging that consultation is not always possible, the collective recommends using the author or creator’s most recent name and avoiding former names if their preference is not known. While this is not necessarily the preference of all trans and gender diverse people, this approach was designed to minimize any potential harm and protect privacy. In some cases, it may be necessary to use a former name in a non-public way to link all works by a single person together. The report also provides coding instructions for this.

**Gender**

RDA provides the option to directly record gender in NARs. Gender and gender identity may also be recorded indirectly (e.g. gendered occupations). The collective recommends that gendered information should not be recorded either directly or indirectly. While working on the document (April 2022), the Program for Cooperative Cataloging (PCC) Ad Hoc Task Group on Recording Gender in Personal Name Authority Records released their revised report recommending that gender not be directly recorded in NARs, stating that NARs are not meant to primarily contain biographical information, but instead only meant to disambiguate between names (Billey et al., 2016). This recommendation has been adopted as official policy. The PCC Task Group on Gender (a successor to the initial ad hoc task group) is currently formulating guidance on indirect recording of gender amongst other issues, including gender-related name changes and gendered terminology in LCSH. Their final report is scheduled to be released in August 2024.

**CONCLUSION**

The Trans Metadata Collective’s document, Metadata Best Practices for Trans and Gender Diverse Resources was initially released in June of 2022. Since its release the report has circulated widely, reaching past 10,000 downloads and has been partially or locally implemented in various GLAMS institutions. After publication, the collective’s focus lies in continuing dissemination of its recommendations to broader professional audiences, encouraging further local implementation, and updating the report when needed.

To achieve in creating accurate metadata for trans and gender diverse communities and their works, metadata workers must take a reflective approach, centering trans and gender diverse information protocols and reciprocally building relationships with those being described when appropriate. The recommendations outlined in this paper consciously steer professionals away from harmful terminology and workflows used in libraries and archives.
Further work is needed to expand these best practices into other institutional and professional spaces, including both cultural heritage and broader information science contexts.

Curating for Contrarian Communities: Data Practices of Anthropogenic Climate Change Skeptics

Wofford, Morgan F. University of Michigan, USA | mwofford@umich.edu
Thomer, Andrea K. University of Arizona, USA | athomer@arizona.edu

ABSTRACT
The open data movement is often touted as a sweeping strategy to democratize science, promote diverse data reuse, facilitate reproducibility, accelerate innovation, and much more. However, the potential perils of open data are seldom examined and discussed in equal measure to these promises. As we continue to invest in open data, we need to study the full spectrum of what open data facilitates in practice, which can then inform future policy and design decisions. This paper aims to address this gap by presenting an investigative digital ethnography of one contrarian community, anthropogenic climate change (ACC) skeptics, to describe how they process, analyze, preserve, and share data. Skeptics often engage in data reuse similar to conventional data reusers, albeit for unconventional purposes and with varying degrees of trust and expertise. The data practices of ACC skeptics challenge the assumption that open data is universally beneficial. These findings carry implications for data repositories and how they might curate data and design databases with this type of reuse in mind.

KEYWORDS
data practices, data repositories, data curation, data reuse, anthropogenic climate change skeptics

INTRODUCTION
One of the purported promises of the open data movement is its democratizing potential, affording people outside of scholarly communities the ability to access and analyze data (Baack, 2015; Cavalier & Kennedy, 2016; Espinosa et al., 2014; Nielsen, 2011; Ricker et al., 2020; Zuiderwijk & Janssen, 2014). Open data activists typically envision a “democratization of information” (Baack, 2015) as a largely positive development. There are numerous examples of these prosocial outcomes, such as citizen groups like the Anti-Eviction Mapping Project and the Mapping Police Violence Database utilizing open government data to support the needs of marginalized communities (Anti-Eviction Mapping Project, 2021; Mapping Police Violence, 2021).

However, open data can also be susceptible to misuse or misinterpretation by various communities. For instance, local governments and private companies often misuse climate data when determining financial climate-related risks, resulting in inaccurate projections (Fiedler et al., 2021). Additionally, during the COVID-19 pandemic, anti-mask proponents employed ‘orthodox visualization methods’ on open government data to bolster their ‘unorthodox arguments’ against mask mandates (Lee et al., 2021). In another example, DNA samples and 3D facial images were utilized to train machine-learning algorithms used by law enforcement agencies to reconstruct suspects’ faces from DNA samples, leading to biased outcomes (Pasquetto, 2018).

Understanding the different ways open data are used and misused is crucial for infrastructural development and supporting appropriate data reuse by scholars and non-scholars alike. These tasks often fall to data repositories managing the discoverability, accessibility, usability, and preservation of datasets housed in their collections. Understanding the diverse data practices of a full range of repository users – even those that may misuse data – is essential in informing design decisions and curatorial activities.

In this paper, we conduct an investigative digital ethnography on a contrarian community (that is, a community that defines itself in opposition to the mainstream and employs misinformation (Ribeiro et al., 2020)) of data reusers -- anthropogenic climate change (ACC) skeptics -- examining their data practices, specifically how they acquire, process, analyze, preserve, and publish/share open climate data. We analyze how ACC skeptics’ data practices compare to traditional academic data practices by comparing them to the primary elements of the USGS’s data lifecycle model (DLM) (Faundeen et al., 2014). We ask: What are ACC skeptics’ data practices and goals? How do these differ from those of academic or traditional data reusers? We find that skeptics’ data reuse is similar to that of traditional data reusers, albeit with different research goals, levels of trust, and expertise. We end with a discussion of the implications of these findings for data repositories, including the need for data misuse policies and designing for diverse user groups.

LITERATURE REVIEW
Open Data and Data Re- and Mis-use
Open data refers to datasets that can be accessed and “freely used, modified, and shared by anyone for any purpose” (Open Knowledge Foundation, n.d.). The promises of open data have been espoused for years, with groups touting its potential to facilitate reproducibility (AlQuraishi & Sorger, 2016; Martens & Vizcaíno, 2017; Stodden et al., 2014), accelerate innovation (Knoppers, 2014; Knoppers et al., 2014), democratize science (Cavalier & Kennedy,
promote collaboration (Pasquetto et al., 2019), and derive new insights from old research (Pasquetto et al., 2019; Rung & Brazma, 2013; Zimmerman, 2003, 2008). Sabina Leonelli suggests that the very allure of open data “lies precisely in the impossibility to predict and quantify their potential as evidence in advance,” reflecting the reality that it is impossible to thoroughly foresee how data will be reused (2013, p. 9). In the United States, the federal government has issued memorandums (Holdren, 2013), executive orders (Obama, 2013), and more binding legislation (Ryan, 2019) that require all federally-funded research to publish non-sensitive data publicly. In response to these potential benefits and governmental mandates, stakeholders have invested in making the promises of open data a reality via initiatives such as the FAIR guiding principles for scientific data management and stewardship (Wilkinson et al., 2016).

The perils of open data are less frequently explored but not disregarded. Philip Mirowski argues that open data may be more readily utilized by those with greater resources, such as corporate data scientists, which could exacerbate existing power imbalances and fail to truly democratize and diversify science (2014, 2018). There is also a well-established literature on indigenous data sovereignty, which addresses the historical harms caused by data collected about indigenous communities and emphasizes community control and ethics rather than maximum openness (CARE Principles, 2022; OCAP, 2022; Radin, 2017; Tsosie et al., 2021). Making data public means that contrarian communities, those that oppose mainstream views or attitudes and often create and spread misinformation, such as ACC skeptics, vaccine skeptics, flat earthers, and eugenicists, can also use the data (Ribeiro et al., 2020). Data creators also have concerns about sharing their data due to the potential for misuse or misinterpretation (Cragin et al., 2010; Sayogo & Pardo, 2013; Tenopir et al., 2015, 2018), as evidenced by instances of misuse as defined by subject matter experts in climate science (Fiedler et al., 2021; Hardy & Jamieson, 2017), genomics (Pasquetto, 2018), ecology (Clavero et al., 2022), and medicine (Jourdain, 2021). Furthermore, the very concept of open data can be weaponized in politicized debates (Levy & Johns, 2016), with partisans in legislative bodies using the perceived non-partisan value of scientific transparency and open data to advance their political agendas. At the same time, the open data requirements are worded, perhaps purposefully, to be impossible to satisfy due to technical infeasibility, lack of resources, or missing privacy, security, and confidentiality exceptions.

Open data facilitate data reuse, defined as the “usage of a dataset by someone other than the data creator” (Pasquetto et al., 2017). Various studies examine who searches for open data, why they do so, and how they reuse data. Most studies focus on academic data reuse practices using data access requests (Coady et al., 2017; Federer, 2019), surveys (Curty et al., 2017; Faniel et al., 2016; Gregory et al., 2020; Tenopir et al., 2011; Yoon & Kim, 2017), and published data citation metrics (Fan et al., 2022; Huang et al., 2015; Khan et al., 2019; Laﬁa et al., 2023; Park et al., 2018; Peters et al., 2017; Piwowar & Vision, 2013; Robinson-Garcia et al., 2017). Several types of data reuse have been identified, including:

- Comparative data reuse: Data are reused for ground-truthing, calibration, comparison, and conﬁrmation (Pasquetto et al., 2019).
- Integrative data reuse: Data are reused to answer new questions, identify patterns, perform meta-analyses, or develop new statistical methods (Pasquetto et al., 2019; Thomer, 2022).
- Reproducibility data reuse: Researchers reuse the same data and analysis methods to verify a study’s findings (Borgman, 2015; Federer, 2019; Pasquetto et al., 2017).
- Infrastructural data reuse: Data are reused to populate a database or repository (Federer, 2019).
- Educational data reuse: Data are reused for educational or instructional purposes (Thomer et al., 2023).

Overwhelmingly, studies that measure the impact and outcome of open data are done by advocates of that infrastructure, leading to a potential for positive biases (Mayernik et al., 2017). Additionally, by focusing on academic impact, they often fail to consider reuses in educational or policy settings (Mayernik et al., 2017).

Another group of studies examines the data practices within different disciplines (Borgman et al., 2015; Faniel et al., 2013, 2020; Faniel & Yakel, 2017; Weber et al., 2013). The goal is to support repositories as they make design decisions to support these intended users (Faniel et al., 2020; Faniel & Yakel, 2017; Kansa, 2012). Repositories intending to serve broader communities have even greater user requirements to consider. The design choices and material forms of data schemas in repositories profoundly impact how “these systems play in the social settings in which they are used” (Thomer & Wickett, 2020).

Climate Science and the Persistent Presence of Skeptics
Climate science is one of many disciplines embracing open data; the Registry of Research Data Repositories lists 131 repositories associated with the keywords “climate” or “climate change” (Re3data, 2014). The majority of climate research focuses on the drivers and effects of ACC, “a statistically significant variation in either the mean
state of the climate or in its variability, persisting for an extended period,” caused by human activity
(VijayaVenkataRaman et al., 2012). Climate scientists use global climate models (GCMs) and simulations to make
projections about the future climate (Edwards, 1999, 2010). As a scientific concept, ACC has reached a level of
scientific consensus that most theories will never attain, with 99.99% of publishing scientists validating its existence
(Powell, 2015). However, despite this relative certainty, ACC skepticism still permeates politics and popular culture,
principally in white, conservative, male-dominated circles (McCright & Dunlap, 2011; Sharman, 2014). This
skepticism could have disastrous consequences if it delays climate change mitigation and adaptation.

At their most extreme, ACC skeptics use climate science’s reliance on models to dismiss the discipline and its
findings as imaginary and politically motivated. In less extreme circumstances, they discover and report errors in
climate data to spark debate and introduce additional uncertainty (Gramling, 2007), or they use and manipulate open
climate data in direct service of their positions and beliefs (Lewandowsky et al., 2016). ACC skeptics use techniques
such as data-dredging or p-hacking, both forms of data analysis misuse, to support their claims (Nissen et al., 2016).
Lewandowsky et al. performed a blind expert test on multiple contrarian claims about climate data and found them
all to be misleading (Lewandowsky et al., 2016). Skeptics present their findings as having the same legitimacy as the
research of thousands of climate scientists. Frank Fischer studied how climate science skeptics interpret scientific
studies, noting that fact-checking and scientific literacy is insufficient in changing their minds; instead, researchers
need to look deeper at how climate skepticism is culturally and historically situated (Fischer, 2019).

METHODS
To gain insights into the data practices of ACC skeptics, we conducted an investigative digital ethnography that
combines methods from digital ethnography (Boellstorff, 2012; Coleman, 2010, 2012; Hine, 2000; Krafft &
Donovan, 2020; Panofsky & Donovan, 2019; Pink et al., 2015) and investigative journalism (Silverman, 2020). The
overall process for conducting an investigative digital ethnography involves identifying relevant topics and artifacts,
ascertaining the media ecosystem and influencers, creating a monitoring environment and strategy, auditing
assumptions, and analyzing findings (Friedberg, 2020). Following conventional digital ethnography methods, we
account for the infrastructures that afford these data practices (Pink et al., 2015). We contextualize these as
knowledge infrastructures that are “robust networks of people, artifacts, and institutions that generate, share, and
maintain specific knowledge about the human and natural worlds” (Edwards, 2010).

Initially, we created social media accounts on Reddit, Twitter, and YouTube and seeded these accounts by following
popular ACC organizations and influencers identified from the DeSmog Disinformation Database (Lay, 2022). We
then engaged with platform affordances, such as viewing, liking, and re-posting content, to influence
recommendation algorithms and expand the monitoring environment. The recommendation algorithms suggested
new accounts to follow through algorithmic-assisted snowball sampling. The final monitoring environment included
40 Twitter accounts, four Facebook groups, two subreddits, and five YouTube channels.

The data collection period lasted from September 2021 through November 2021, totaling 75 hours. When open data
were discussed or reused, we archived the webpage. If posts linked to blogs or organizations that mentioned open
data, those websites and subsequent comments were archived. YouTube videos were transcribed. Daily memos were
written during the data collection and analysis periods. In total, 189 articles and posts were archived, 17 screenshots
were taken, and 19 pages of memos were written.

All the data artifacts were uploaded into NVivo for qualitative coding in January 2022. We synthesized themes
across the data using grounded theory (Glaser & Strauss, 1967) adapted for social media analysis (Postill & Pink,
2012), inductively coding the data for emergent themes. While doing this, we compiled lists of data reusers,
instances of dataset reuse, analytical tools mentioned by reusers and so on. These themes were then coded into
higher-level concepts, constructing theories grounded in the data (Charmaz, 2014). We then organized our findings
about ACC skeptics’ data practices according to the USGS DLM primary model elements to compare these
contrarian practices to normative data practices (Faundeen et al., 2014). We chose this model because it highlights
the relationship between data management activities and research project workflows, allowing us to focus on how
ACC skeptics interact with data repositories and manage their data. Moreover, the model is designed for types of
data that ACC skeptics are likely to reuse (e.g., from the earth and environmental sciences). The primary data life
cycle stages include plan, acquire, process, analyze, preserve, and publish/share. Within the analyze concept, we
additionally coded for the way in which data was reused for analysis, for instance, comparative or integrative as
appropriate (Pasquetto et al., 2019; Thomer, 2022). If instances of data reuse did not fit within these categories, new
codes were created.

FINDINGS
The ACC Skeptic Community
Across platforms, we observed 77 data reusers posting on their social media accounts, authoring blog posts, and
creating websites. Notably, the majority of identifiable influencers in this contrarian community are conservative,
Influencers are predominantly located in the United States, Canada, Australia, and England. Some of them have direct ties to the oil, gas, and coal industries as well as the tobacco industry. Three of the individuals were part of the Trump Administration, working in various agencies such as the Environmental Protection Agency (EPA), National Security Council (NSC), National Oceanic and Atmospheric Administration (NOAA), and White House Office of Science and Technology Policy (OSTP).

Generally, reusers are highly educated, many stating they have PhDs. They claim expertise in a wide range of disciplines, including aerospace engineering, atmospheric science, chemistry, climatology, economics, forestry, geography, geophysical science, hydrology, meteorology, modern history, philosophy, physics, and political science. We observed an overlap between ACC skeptics and anti-vaxxers, anti-maskers, and skeptics of the 2020 U.S. presidential election results. Though here we focus on their analysis of climate data, we also found that they apply their data literacy to other public datasets, including 2020 U.S. presidential election data, as well as COVID-19 data.

Plan & Acquire
While the USGS DLM’s lifecycle begins with planning work, we did not find that our users’ planned their projects publicly online. Instead, the majority of early lifecycle discussions focused on the acquisition and evaluation of public data and data repositories.

What Data do ACC Skeptics Reuse?
We observed ACC skeptics reuse 61 datasets (Figure 1) from 45 data repositories; of these, ACC skeptics most frequently reuse observational datasets about temperature because the core assumption of ACC rests on the idea that global temperatures are increasing. As a result, skeptics often rely on observational temperature datasets to challenge this assertion and attempt to undermine it in various ways. The top five most reused datasets are as follows:

- **HadCRUT** from the Met Office Hadley Centre and the Climatic Research Unit (CRU) (found in 24 documents) (Brohan et al., 2006; Morice et al., 2012, 2021). HadCRUT combines a sea surface temperature (SST) dataset and a land surface air temperature dataset. Often, skeptics state that these data are less trustworthy because of CRU’s involvement with Climategate, a controversy where an ACC skeptic published hacked emails from CRU and cited them as evidence that climate scientists had manipulated data to make global warming appear worse (Leiserowitz et al., 2013).

- **Global Temperature Report** from The University of Alabama in Huntsville Earth System Science Center (found in 13 documents) (Christy & Spencer, 2022). Two ACC skeptics, John R. Christy, and Roy W. Spencer, created this dataset. This global temperature dataset is derived from NOAA’s TIROS-N satellite microwave data and shows less extreme increases in temperature than similar datasets.

- **Goddard Institute for Space Studies Surface Temperature (GISTEMP) Analysis Dataset** from NASA (found in nine documents) (GISTEMP Team, 2022). GISTEMP is comparable to the HadCRUT dataset in combining a land-surface air temperature dataset and an SST dataset to create a global temperature dataset, and the two are often compared.

- **Global Historical Climatology Network monthly (GHCNm) Dataset** from NOAA’s National Center for Environmental Information (NCEI) (found in eight documents) (Menne et al., 2018). This dataset provides monthly climate summaries from stations around the world. Climate skeptics critique this dataset saying data are skewed due to urbanization and homogenization.

An additional 15 temperature datasets are found in the sample (see the supplementary material at https://hdl.handle.net/2027.42/176905 for the complete list).

Two datasets are reused in six documents, tying each other for the fifth most reused dataset. Unlike the previous four datasets, neither are temperature datasets. They include:

- **NOAA’s Global Monitoring Laboratory (GML) Earth - System Research Laboratories Monthly Average Mauna Loa CO2** (Tans & Keeling, 2022). This dataset shows monthly mean measurements of atmospheric CO2 at the Mauna Loa Observatory in Hawaii. Skeptics use this dataset to examine trends in CO2 and test for correlation with other variables. There is one other CO2 dataset in the sample.

- **National Snow & Ice Data Center’s Multisensor Analyzed Sea Ice Extent – Northern Hemisphere (MASIE-NH)** (U.S. National Ice Center & NSIDC, 2010). MASIE-NH provides a graphical view of sea ice extent. Skeptics use this dataset to explore trends in sea ice over time, suggesting the cause of changes are exaggerated or seasonal. Three other sea ice datasets are in the sample.

A related research topic to sea ice is the exploration of sea level trends, mainly arguing that the rate of sea level rise is not increasing. The sample included four sea-level datasets.
Another popular research topic is natural disaster rates, including fires, hurricanes, droughts, diseases, and associated climate-related death data. In this area of research, ten different datasets were reused. Skeptics commonly try to show that natural disaster rates are not increasing or attribute the observed disaster rate increase to changes in disaster categorization and reporting rates.

Skeptics also suggest alternative causes of climate change. These potential climate change drivers include the sun, the ocean’s oscillations, and atmospheric water vapor. The sample contains five solar datasets examining sunspot numbers, total solar irradiance, and outgoing longwave radiation. Six datasets look at the ocean’s oscillations. Only one dataset records atmospheric water vapor.

The last common research topic is investigations into the capabilities of fossil fuels and renewable energies. The sample contains seven energy datasets representing energy grid conditions, electricity production data, crude oil production, and fossil-fuel CO2 emissions. Quality of life data, like world development indicators or food production, are often used alongside fossil fuel usage to insinuate that quality of life has increased because of fossil fuels.

Figure 1: Dataset reuse frequency in collected documents. Due to space constraints, we only list the top 5 most reused datasets; see the supplementary material at https://hdl.handle.net/2027.42/176905 for the complete list. Frequency is calculated as the number of documents the dataset appears in.

**How do ACC Skeptics Evaluate Data and Data Repositories?**

In this contrarian community, not all data are created equal; unadjusted or “raw” data are considered superior to all other forms of knowledge because they are the least affected by human subjectivity. By “raw,” skeptics refer to data directly collected from instruments with no additional processing, adjustments, homogenization, or manipulation. Overwhelmingly, ACC skeptics favored reusing observational data over other types of data. Climate science, as a discipline, relies on GCMs rather than observational data, which ACC skeptics prefer. Most of the observed ACC skeptics did not engage sophisticatedly with GCMs enough to demonstrate mainstream climate science literacy. Instead, they reject these models outright, considering them inferior to observational data. Observational data are thus often used to critique proxy data and climate model projections.

Consequently, when acquiring data, some ACC skeptics closely examine data repositories, documentation, curatorial decisions, and scholarly products to find processing that has “contaminated” the raw data. For instance, in a Reddit post, a skeptic critiques the GHCN-M dataset by directly quoting the dataset’s documentation (Menne et al., 2018).

```
...in the introduction to the data (CDRP-ATBD-0859 Rev 1 GHCN-M Mean Temperature-v4.pdf) it states: 'Data are collected from NOAA in situ networks as well as other national and international providers. They are subjected to a series of processes that combine data from various sources, perform quality control, homogeneity corrections, and output the data for customer access and permanent archive.'

And their readme.txt from their ftp site says in the Introduction: '...The greatest difference from previous version is a greatly expanded set of stations based on the large data holdings in GHCN-Daily as well as data collected as part of the International Surface Temperature Initiative databank (ISTI; Rennie et al. 2014).'
```
ACC skeptics also note when different versions of datasets will be removed or no longer supported actively by repositories and accuse repository staff of changing or removing data to support the theory of ACC. If available, they compare different versions of datasets to note changes using the Wayback Machine.

In the most extreme cases of curatorial oversight, skeptics contact the data repository to question a dataset’s limitations and intended uses. For instance, one ACC skeptic discusses repository employees by name from the Centre for Research on Epidemiology of Disasters EM-DATA International Disaster Database, accusing them of endorsing a publication that contradicts the data’s recommended use. Within the blog post, the author includes correspondence with repository employees.

Even when ACC skeptics are not accusing repositories of intentionally altering data for political purposes, they often analyze curatorial decisions and documentation for their own reuse. For example, the website Climate4You compares differences in sea surface temperature (SST) using two different datasets, HadSST3 and UAHv6 and notes how changes in curatorial activities in both datasets affect their analysis. However, not all ACC skeptics adhere to appropriate data usage and documentation provided by data repositories in their analyses. For instance, the NSIDC recommends against using the MASIE-NH dataset to compare sea ice trends over time, suggesting instead using the NSIDC Sea Ice Index on a monthly, not daily, basis. Nevertheless, despite the repository’s recommendations, Ron Clutz compares MASIE-NH data on specific days in different years in a Science Matters blog post.

**Process**

In the USGS DLM, the next lifecycle phase is processing: this includes data cleaning, data element definition, dataset integration, and calibration to prepare data for analysis. We found limited descriptions of data processing by ACC skeptics for perhaps two compounding reasons. Firstly, many data reusers did not publicly publish or write about their data processing activities. Secondly, as shown in the acquire step, skeptics often disparage any data processing that researchers or repositories carry out on the data, valorizing “raw” data. When ACC skeptics’ data processing activities are made public, they often are not extensive, perhaps because of these beliefs.

That said, one common act of processing is converting data files to make them more accessible and computable in spreadsheets. Zoe Phin typically uses more accessible files in her published data reuse blog posts, but does not always convert data files for her own work. For instance, when examining albedo data she uses the netCDF file provided by NASA Earth Data. However, when sharing data with others in her comments, she converts the original netCDF file to a plain text file for ease of access by less technical users. Nowadays, data repositories often provide various file formats, including CSV and TXT files, making the need to convert file formats unnecessary. For example, in a CO2Science blog post, the author uses the HADCRUT CSV version of the dataset over the netCDF version, along with the TXT file of CO2 data from NASA.

**Analyze**

In the USGS DLM, analyze encompasses the activities undertaken by ACC skeptics as they explore and interpret the data they have selected, ultimately drawing their conclusions.

We separate analytical activities into the data reuse typology discussed in the literature review and methods section, which includes comparative or integrative data reuse. We found instances of comparative and integrative reuse (Pasquetto et al., 2019; Thomer, 2022). We additionally observed a new kind of data reuse which we call quality assessment reuse. We describe each of these below.

Integrative data reuse entails reusing data for new analyses to “identify patterns, correlations, or causal relationships” (Pasquetto et al., 2019). Integrative data reuse can include meta-analyses or novel statistical analyses. Within the ACC skepticism community, integrative data reuse is widespread and includes identifying patterns in observational data and testing for correlation between variables. ACC skeptics use observational data to identify trends in temperature, CO2 levels, sea ice area, sea-level rise, and natural disasters. Many of their findings directly contradict the scientific consensus: global temperature is cooling, sea ice size is increasing, or natural disaster rates are decreasing. Others assert that there are no identifiable trends in these variables. Others admit to identifiable and even statistically significant trends that support the scientific consensus but assert that they cannot be attributed to anthropogenic CO2 emissions. Finally, some evaluate the dataset and conclude that the data are flawed and unreliable due to changes in measurement practices or other perceived errors. These options lead to the almost inevitable contradiction of the scientific consensus regardless of the data used.

Comparative data reuse consists of reusing data “to assess similarities and differences for purposes such as ground-truthing, calibration, and experimental controls” (Pasquetto et al., 2019). Comparative data reuse within the ACC
skepticism community includes using observational data to evaluate model projections and proxy data. It also encompasses the comparison of similar datasets from different organizations or different versions of the same dataset. For instance, observational data are often used to test other types of what ACC skeptics perceive as inferior data, like climate model outputs and proxy measurements for temperature and CO2. One skeptic described observational data as “ground truth data” or “information provided by direct observation as opposed to information provided by inference.”

Finally, ACC skeptics reuse data in a way that does not straightforwardly fit into existing typologies, which we call **quality assessment data reuse.** While similar to reuse for reproducibility, it is distinct because they are not trying to reproduce the findings of a publication; rather, they solely analyze the quality of a dataset. For instance, one contrarian site, surfacstations.org, run by Anthony Watts, organized volunteers to survey temperature stations to document “biases and errors through faulty siting, encroachments, or maintenance issues.” Even though Watts showed these biases and errors to be statistically insignificant, he continues to critique the GHCN dataset publicly. The ACC skeptic website Climate4You contains perhaps the best example of quality assessment reuse in our sample. The website contains a global temperature page, which analyzes five global temperature datasets in a multitude of ways, including linear and polynomial regression for different periods of time. Here we focus on one example of analysis, which the site calls testing for temporal stability or each dataset’s internal degree of stability over time. The site does this by “plotting the net change in their global temperature record” between the May 2008 version of a dataset and the October 2021 version of the same dataset. By comparing the temporal stability of datasets, Climate4You asserts that,

> “….it is not possible to conclude which of the above five databases represents the best estimate on global temperature variations. The answer to this question remains elusive. All five databases are the result of much painstaking work, and they all represent admirable attempts towards establishing an estimate of recent global temperature changes. At the same time it should however be noted, that a temperature record which keeps on changing the past hardly can qualify as being correct.”

**Tools for Analysis**

Most skeptics rely on their own software, like Excel or R, to analyze data and create visualizations. Andy May, who analyzes data using R and Excel, states that “R makes it easy to do the calculation, but it is unsatisfying since we don’t get much understanding from running it or from the output.” This duplication of data analysis aligns with the skeptical values of teaching others how to reuse data and questioning assumptions behind analysis.

Skeptics also take advantage of interactive data analysis tools provided by data repositories, ACC skeptics’ organizations, and agnostic groups (Figure 2). This means that skeptics are not solely reliant on official data analysis tools but have other options that provide additional flexibility and interoperability with various datasets. Wood for Trees is the most popular tool created by an ACC agnostic software engineer, hosting “C++ software tools for analysis and graphing of [historical climate] time series data, and an interactive graph generator where users can play with different ways of analyzing data.” The home page asserts that,

> “It’s not the place of this Web site (or anyone else) to tell you the answers, even if I could! This is just a tool to help you dig into the data to help you form your own opinions. Whatever you decide the most important thing is that you learned what the issues in analysis are and how to test your ideas against real data.”

This statement reflects a mindset common in ACC skeptics that devalues expertise and emphasizes trusting one’s own data analysis. However, Clark follows this assertion with the following warning “with sharp tools comes great responsibility…beware of short, cherry-picked trends.” This is more guidance than skeptical tools offer.

The main C++ program for Wood for Trees is the analysis tool that performs a variety of processes on time-series data formats before outputting the data to a format suitable for plotting with Gnuplot. The program can read a variety of datasets, including the major global temperature datasets, Mauna Loa CO2 monthly average, PDO index, AMO index, and NSIDC Sea Ice Index. Recently, Wood for Trees added the ability for linear least-squares regression. Still, Clark notes “that it can be fairly dangerous…depending on your preconceptions, by picking your start and end times carefully, you can now ‘prove’ whatever you want with temperature trends.” This affordance, perhaps, contributes to its popularity with ACC skeptics.

RimFrost.no and Sealevel.info are two other tools that provide interactive database visualization tools incorporating numerous open datasets. RimFrost.no, “a unique collection of essential climate info,” provides a tool to graphically represent thousands of datasets, including temperature data, ice data “CO2 emissions, CO2-in-the-air measurements, river discharge data, precipitation intensity data, glacier mass balances, ocean energy and ocean water levels, sunspot numbers, and skiing conditions.” Sealevel.info is a website created by an ACC skeptic to provide a similar
tool as Wood for Trees but for sea-level data. The “spreadsheets...consolidate data from NOAA, PSMSL, and other sources to simplify examination of tide-gauge data for long term sea-level trend analysis.”

The seven other data analysis tools are associated with specific data repositories or governmental agencies. Generally, these have more limitations than the tools above, only including data from their own repository. The most used of these is NSIDC’s Chartic Interactive Sea Ice Graph, which visualizes the Arctic and Antarctic yearly seasonal cycles of sea ice extent beginning in 1979, which is the start of the satellite record.

![Figure 2: Frequency of interactive database visualization tool use in collected documents. Frequency is calculated as the number of documents the tool is used in.](image)

**Preserve**

The preserve stage of the USGS DLM involves activities related to storing data for long-term use and accessibility. This includes creating documentation and metadata, using accessible storage file formats, and creating supplementary products for preservation.

Many skeptical organizations utilize data to populate their websites and databases, providing convenient access to data in one location. When datasets are shared, application-neutral storage formats such as CSV files are commonly used. For example, Wood for Trees provides “raw” data in tabular plain-text files accompanied by metadata. The metadata in the file includes information on who processed the data (e.g., www.woodfortrees.org), the original source of the data (e.g., NASA Goddard Institute for Space Studies), a link to the original data (e.g., data.giss.nasa.gov/gistemp), the file name (e.g., GLB.Ts.txt), and a brief description of the data (e.g., Time series (gistemp) from 1880 to 2023.08). Other websites’ file formats are more diverse. For instance, SeaLevel.info provides JSON files with extensive metadata, copies of NOAA’s data in CSV files, spreadsheets of tabulated data in Microsoft Excel HTML format, and documentation for metadata in plain-text files.

Other websites and groups, such as Climate4You and Going Green Canada, rely on data repositories only providing links to publicly-available datasets without creating their own databases. They often choose to provide links to the documentation of these datasets to promote further understanding of the data. However, relying on these data repositories for data preservation means that any changes made by the official organization can affect the availability of data. Data and documentation may be moved to different sites, such as when many NOAA datasets were moved from NCDC to NCEI. In other cases, data repositories may remove certain datasets due to errors, newer versions, or administrative changes. As a result, links to datasets and documentation on these sites may occasionally be dead as site managers fail to update the links.

**Publish/Share**

In the USGS DLM, activities in the publish/share phase conventionally include the publication of findings in peer-reviewed journals as well as the distribution of data online. However, within the sample, ACC skeptics, with one exception, never published in peer-reviewed journals. Instead, they post their findings in blog posts, skeptical conferences, and on social media.

Frequently blog posts with data reuse cases have extremely long comment sections, reaching up to hundreds of pages. Commenters include ACC skeptics and some non-skeptics, although their specific stance on the issue is often difficult to determine. When errors are pointed out that the data reuser agrees with, the work is frequently changed. For instance, one skeptic responds to an error in his figure by stating, “Thank you very much for finding my labeling
error in Figure 10 that inadvertently switched the labels for land and deep ocean, ending up disagreeing with my own calculations. I updated the PDF above to correct this error.” In a way, the comments section functions as peer review. Commenters provide constructive critique, and reusers revise their work accordingly.

When discussing data sharing or publishing efforts, ACC skeptics emphasize the importance of involving more people in reusing climate data. If a commenter wants to reproduce work, the reuser will provide data, instructions, guidance, and in some cases, the code used. Very occasionally, data reusers refuse to provide data and code when asked for by commenters. One data reuser, Willis Eschenbach, states that the size of the data, along with their unwieldiness and lack of documentation, make them difficult to reuse. Instead, he would “MUCH rather do new and interesting research than spend time beating my code into usable shape.” While Eschenbach’s refusal may be due to flawed code or deliberate misuse, it seems just as likely that it results from the time commitment needed to make code understandable and reusable. However, he does provide the commenter with a folder with the basic functions he used. As another data reuser mentions in the comments of her blog post, “making small mistakes gets people involved. I think I’ll do it more often. I just made 2 more experts.”

**DISCUSSION**

**ACC Skeptics’ Data Practices in Existing Lifecycle Models and Reuse Typologies**

ACC skeptics’ data practices align with those described by the USGS DLM in the sense that skeptics acquire, process, analyze, preserve, and publish/share data, often in that order. However, skeptics diverge from traditional researchers in their data evaluation, research goals, criteria for publishable findings, and publication outlets. First, very rarely do ACC skeptics collect their own data and thus are entirely reliant on data they find in open access repositories. Second, the end research goal of many ACC skeptics is to discredit data by finding alleged errors. Additionally, skeptics do not process their data to the extent that traditional researchers would, perhaps, in part because they view mainstream processing activities as contaminating “raw” data, potentially leading to biases. Furthermore, ACC skeptics rarely publish in peer-reviewed journals; instead, they often post or present their findings in blog posts, skeptical conferences, and on social media.

Several studies have identified and categorized different types of scientific data reuse (Coady et al., 2017; Federer, 2019; Gregory et al., 2020; Pasquetto et al., 2019). These typologies are based on the data reuse practices of typical data reusers, such as academic researchers. Do the data reuse types found in the ACC skepticism community fit within these typologies? Largely, the answer is yes, with some caveats. Within the ACC skepticism community, data reuse types can be broadly classified into integrative data reuse (Pasquetto et al., 2019), comparative data reuse (Pasquetto et al., 2019), quality assessment data reuse, and infrastructural data reuse (Federer, 2019).

Integrative data reuse, as defined by Pasquetto et al. (2019), refers to the use of datasets for new analyses with the aim of identifying patterns, correlations, or causal relationships. Integrative reuse is widely observed within the ACC skepticism community, often involving the identification of patterns in observational data and testing for correlations between variables. However, it is a less common practice in the academic communities studied in the Pasquetto et al. paper. Pasquetto et al. argued that significant amounts of tacit knowledge are needed to facilitate effective integrative reuse; we speculate that because ACC skeptics are not performing integrative data reuse in the normative epistemological context of climate science, they do not share mainstream scientists’ qualms about integrating other people’s data. They do not consider tacit knowledge valid and do not require it for integrative reuse. Thus, integrative reuse is more common in ACC skeptic communities than in mainstream.

Comparative data reuse entails the practice of utilizing data to assess similarities and differences for various purposes, such as ground-truthing, calibration, and experimental controls (Pasquetto et al., 2019). Pasquetto et al. found comparative reuse to be common in the academic communities they studied; we similarly found that comparative data reuse is a prevalent and routine practice within the ACC skepticism community. Skeptics use observational data to evaluate model projections and proxy data, as well as to compare similar datasets from different organizations or different versions of the same dataset.

We observed on type of data reuse not found in existing typologies. In **quality assessment data reuse**, skeptics analyze the quality of a dataset to identify flaws or weaknesses, as shown in tests for temporal stability or surfacestations.org surveys. This differs from quality assessment done by the mainstream climate science community, where the quality of their selected data is assessed prior to reuse. For mainstream climate scientists, this assessment is rarely the final public output of the reuse. Additionally, ACC skeptics often conduct these quality assessments solely to discredit the data and climate science in its entirety.

Finally, we additionally observed instances of infrastructural data reuse, which involves reusing one or more datasets to populate a database or repository (Federer, 2019). ACC skeptics reuse datasets to populate databases on multiple sites, including Climate4You, SeaLevel.info, and CO2Science. They bring together datasets from various agencies and universities that are often siloed from one another into one accessible database. This serves a larger
goal of creating an alternative knowledge infrastructure that mimics and takes advantage of climate science’s mainstream knowledge infrastructure in an attempt to weaken it. We term this infrastructure a **parasitic knowledge infrastructure** that builds on the back of the mainstream climate science knowledge infrastructure (Wofford, 2022). A parasitic knowledge infrastructure generates, shares, and maintains its knowledge using components of another knowledge infrastructure while simultaneously weakening that infrastructure it relies upon. The “hypertransparency [of] open data, open code, commodity software tools, and alternative publication venues” allows skeptics to selectively use these artifacts (Edwards, 2019, p. 21).

**Implications for Data Repositories**

Our findings show that ACC skeptics frequently evaluate and interact with data repositories. Data will inevitably be reused in ways repositories do not anticipate and, perhaps, do not agree with. This will be difficult, if not impossible, to avoid through any act of design or curation. Nonetheless, our study has implications for repositories in dealing with contrarian reusers. While these implications primarily apply to scientific data repositories, they may also hold relevance for other contexts, disciplines, or data types. Future research is needed to investigate the interactions between contrarian communities and different types of data repositories.

First, repositories must consider how they might handle the misuse of data and develop policies accordingly. Throughout our work, we have struggled with how to characterize ACC skeptics’ use of data. The reusers we observed would not consider their work misuse of data, but certainly, many (if not all) mainstream scientists and data curators see ACC skeptic’s practices as inappropriate or flawed. Data repositories and curators are likely not in a position to act as arbiters for truth, but it is essential to recognize that repositories, like all technologies, are not neutral. Curatorial policies have the power to shape not just data reuse but public perceptions of scholarship.

Second, it is crucial to recognize that trust in a repository, its curators, and its data are not guaranteed. In fact, certain communities of reusers will come to a repository with high degrees of distrust. This distrust is not limited to contrarian communities. It may also be seen in other contexts, such as communities in cities expressing distrust in data collection and representation (Yoon & Copeland, 2020) or environmental justice groups distrusting federal data repositories due to perceived ties with polluting companies. Previous studies have linked more traditional data reusers’ trust in repositories with “organizational attributes, user communities (recommendations and frequent use), past experiences, repository processes (documentation, data cleaning, and quality checking), and users’ perception of the repository roles” (Yoon, 2014, p. 17). ACC skeptics bring up these factors when discussing their level of trust in repositories. Often data reusers lose trust in repositories due to validity errors or missing variables. Thorough and transparent documentation thus enhances trust and helps avoid violations in the first place (Yoon, 2017). However, even with increased documentation and decreased errors, it is unlikely that ACC skeptics would stop questioning and critiquing repositories. At the same time, these steps would give ACC skeptics less fodder for skepticism.

Furthermore, data repositories should be designed with various potential user groups in mind, even if all reuse cases cannot be predicted. Different user groups will come to the repository with various levels of expertise and goals; subsequently, they will interact with the repository and data differently. Data and tools, even if not publicized, will be found by non-experts. Because of this, repositories should design tools that do not easily afford misuse, even, in some cases, at the expense of flexibility. Yoon et al. suggest using data intermediaries to empower prosocial communities with limited resources to build data literacy and capacity (2018). Data intermediaries are agents positioned between two other agents in a data supply-demand chain that facilitate the reuse of data (Schalkwyk et al., 2015; Yoon et al., 2018). In this case, however, data intermediaries could be used to understand how data are being reused and, with contrarian communities, to decrease the likelihood of data misuse.

**CONCLUSION AND FUTURE WORK**

This paper examines the data practices of one contrarian community of data reusers, ACC skeptics. These practices are made possible through the parasitic relationship that exists between the skeptics’ knowledge infrastructure and the mainstream climate science knowledge infrastructure and its increased openness. In future work, we will further develop the concept of parasitic knowledge infrastructures and how contrarian knowledge infrastructures can simultaneously rely on and weaken consensus-based knowledge infrastructures through this case study. Other research, soon to be published by our team, looks at how three different contrarian communities, pro-life activists, Young Earth Creations, and ACC skeptics, engage with scientific values and norms (e.g., objectivity), standards (e.g., uncertainty), validation processes (e.g., consensus), and artifacts (Pasquetto et al., 2023). Finally, we hope to see whether this parasitic relationship distinguishes skeptics’ knowledge practices from other forms of public-led epistemic practices, such as those seen in environmental justice groups.

Hyper-Local Fear of Crime: Identifying Linguistic Cues of Fear in Crime Talk on Reddit

Wu, Qunfang

Syracuse University, USA | jjhemsle@syr.edu

ABSTRACT
The fear of crime is an emotional response individuals have toward crime or the anticipation related to being the victim of crime. The increasing exposure to crime information presents considerable risks to people’s psychological health and well-being. Nevertheless, the fear of crime in online discourses is under-researched despite abundant conversations about crime. This work presents a mixed-methods study to comprehend how people disclose the fear of crime and what linguistic content or cues are associated with the fear. We gathered conversations about crime in the Baltimore subreddit. The content analysis revealed a necessity to differentiate between “experienced” and “expressive” fear of crime. The regression modeling identified strong factors related to the fear of crime, such as negative sentiment, objective expression, and first-person pronouns. This work extends the conceptualization of the fear of crime in online discourses and suggests potential ways to detect the fear automatically.

KEYWORDS
Fear of crime; logistic regression; emotion detection; Reddit; online discourse

INTRODUCTION
Hyperlocal social media, such as Nextdoor, Amazon Neighbors, Reddit, and Facebook groups, facilitate users to be exposed to, or actively participate in, conversations about crime. Studies have demonstrated that people collectively engage in conversations about crime through such platforms. For instance, people shared crime information with their neighbors (Masden, Grevet, Grinter, Gilbert, & Edwards, 2014; S. L. Erete, 2013), discussed crime prevention matters in community governance organizations (S. Erete & Burrell, 2017; S. L. Erete, 2015), and conversed with local municipal police departments (Williams et al., 2018; Wu & Huang, 2020). Nevertheless, the increasing exposure to crime-related information can lead to people to feel greater fear of crime and, thus, pose a risk to their well-being (Moore, 2019). This signals a need to more accurately conceptualize the fear of crime and mitigate its negative effects. This would benefit people’s well-being and support their ability to maintain routine activities (Ghandeharioun, McDuff, Czerwinski, & Rowan, 2019).

Generally speaking, the fear of crime is an emotional reaction people have toward crime or the anticipation related to being the victim of crime (Ferraro, 1995). To a lesser degree, studies have begun to explore how Information and Communication Technologies (ICTs) can assist in mediating fear of crime (Sachdeva & Kumaraguru, 2015; Blom et al., 2010; Karusala & Kumar, 2017). Nevertheless, the disclosure of the fear of crime in online discourses is under-researched despite the public’s extensive crime-related conversations.

To address this gap, we sought to unpack the fear of crime in online discourses. Specifically, we employed a linguistic approach to comprehend the types of fear of crime disclosed in people’s online conversations about crime and the linguistic features associated with such disclosures. We chose the local subreddit r/baltimore (www.reddit.com/r/baltimore/) as the research site where crime is a prevalent topic. Using crime-related conversation threads collected from r/baltimore, we initially conducted manual coding on 2,000 comments and generated a two-tier code schema for fear of crime disclosure. Subsequently, we selected linguistic features in comments that might be linked to the fear of crime and constructed logistic regression models to examine their relationships. We discovered that users disclosed two types of fear: “experienced” and “expressive”; the regression models revealed that the most pertinent variables to the fear of crime were negative sentiment, objective expression, and i personal pronouns. Finally, we propose future directions to investigate the fear of crime online, such as further exploring the cognitive dimension of fear of crime in social media settings.

RELATED WORK
What is the fear of crime?
Earlier survey studies have found that the fear of crime is a common experience among individuals (Hough, 1995; Kershaw et al., 2000; Koffman, 1996). Studies have conceptualized the fear of crime as diffuse anxiety toward crime or the anticipated risk of being the victim of crime (Gray, Jackson, & Farrall, 2008; Ferraro, 1995). The anticipated risk is a cognitive judgment, where people assess crime rates and the probability of being a target. These studies measured the fear of crime by inquiring respondents questions such as how secure they feel being alone in their neighborhood at night.

To differentiate the perceived risk of victimization and the emotional experience of fearfulness, researchers employed the concept of “awareness of crime” to describe three dimensions involved in fear of crime, namely
“cognitive,” “affective,” and “behavioral” (Fattah & Sacco, 2012; Jarrett-Luck, 2015). Moreover, Innes (Innes, 2004) proposed a “signal crimes” perspective to analyze the disclosure of fear of crime in people’s narratives, including interpreting crime incidents (“expression”), assessing actual or potential threats (“content”), and modifying behaviors (“effect”) (Innes, 2004).

However, Jackson criticized prior studies that had defined fear of crime as a diffuse anxiety toward crime and measured the perceived probability of risks rather than actual experiences in individual lives (Jackson, 2015). To address the criticized issue, Farrall proposed another measurement, which focused on “instances of worry” (Farrall & Gadd, 2004). This included everyday experiences of worrying about crime (Farrall & Gadd, 2004), and asked about both the frequency and the intensity of the fear of crime.

Gouseti summarized different definitions into two types of fear of crime: “expressive” fear and “experienced” fear (Gouseti, 2016). Expressive fear is mediated by and through diffuse anxiety towards vague risks, such as those arising from the social, political, cultural, and financial transformations of late modernity. Experienced fear is associated with the tangible experiences people have with particular criminal incidents or having been victims of crime in the past (Gouseti, 2016).

Scholars have various definitions and methods of measuring the fear of crime, yet they all concur that it encompasses both emotional and cognitive aspects. Previous studies have largely relied on survey questionnaires to understand the fear of crime. To gain insight into the disclosure of the fear of crime in online discourses, this study draws upon (Ferraro, 1995)’s definition, which encompasses both emotional and cognitive components.

The fear of crime disclosure in online conversations
With the proliferation of public discourses about crime on ICTs (e.g., Nextdoor and Facebook Neighborhood groups), it has been observed to have negative effects on people (Lane & Meeker, 2003; Weitzer & Kubrin, 2004). Articles have reported that crime-related information on ICTs can induce fear and reinforce stereotypes across various dimensions, such as race, geographic location, and more (Molla, 2019; Lustbader, 2019). Powell found that the extensive discussion of a crime incident (the disappearance of Gillian “Jill” Meagher) on Twitter created a misconception among the public that random violence can occur anywhere, and anyone can be a victim (Powell, Overington, & Hamilton, 2018). Therefore, it is essential to comprehend people’s fear of crime in the context of crime-related discourses in online spaces and to mitigate the adverse effects on people.

Previous studies have employed survey instruments to identify various factors associated with fear of crime, including but not limited to gender, age, race, socioeconomic status, crime rate, police presence, physical cues, information sources, social support networks, neighborhood satisfaction, and collective efficacy (e.g., Adams & Serpe, 2000; Visser, Scholte, & Scheepers, 2013; Yuan & McNeeley, 2017; Weitzer & Kubrin, 2004). These findings were primarily based on self-reported data in offline contexts.

To the best of our knowledge, there is a dearth of scholarship conceptualizing the fear of crime in online discourses. A pertinent study conducted by Sachdeva et al. (Sachdeva & Kumaraguru, 2015) identified the lexicons in Indian residents’ posts and comments on the Facebook page of Bangalore City Police. The results suggested that frequent keywords, such as fear, concern, worried, trouble, notice of, and issue, indicated residents’ fear or concerns toward crime and could be applied to monitor public voices and build community policing. However, the proposed keywords did not capture the fear of crime adequately, based on scholars’ definitions. Our work builds on prior work that defined and measured the fear of crime offline and online but focuses on the online discourses about crime. Our first research question is: What kinds of fear of crime are disclosed in online conversations?

The Fear Emotion Detection
In the online environment, the presence of fear of crime can be identified through the analysis of linguistic patterns or cues present in online discourses. Below we review existing methods that detected the fear emotion in textual data.

According to Ekman (Ekman, 1992), fear is one of the six basic emotion categories, alongside happiness, sadness, anger, disgust, and surprise. A considerable body of research has investigated supervised and unsupervised methods for classifying the six emotion types in textual datasets (e.g., Bostan & Klinger, 2018; Islam, Mercer, & Xiao, 2019). However, prior work has demonstrated that detecting the fear emotion is more challenging than other emotions. This is due to two primary factors. Firstly, in some corpora, the fear emotion’s annotation results have exhibited lower inter-coder agreement than other emotion categories (Schuff, Barnes, Mohme, Pado, & Klinger, 2017; Torkildson, Starbird, & Aragon, 2014). Secondly, the disclosure of fear is normally scarce, unlike happiness and anger, which are frequently expressed in text (Bostan & Klinger, 2018; Ghazi, Inkpen, & Szpakowicz, 2015). Bostan’s study (Bostan & Klinger, 2018), which compared 14 pre-labeled corpora for emotion classification, showed that less frequent emotions, such as fear, achieved poorer classification performance.
There is an increasing body of research exploring situational expressions in public discourses, with the aim of better understanding human discourse patterns and monitoring emergencies and trends in large-scale data, such as self-disclosure (F.-Y. Wang, Carley, Zeng, & Mao, 2007), mental health discourses (De Choudhury, Sharma, Logar, Ekhout, & Nielsen, 2017), and crisis discourses (Wiebe & Riloff, 2005; Sen, Rudra, & Ghosh, 2015). Among these works, detecting situational awareness on social media during mass emergency events (Lamb, Paul, & Dredze, 2013; Verma et al., 2011; Sen et al., 2015) is most pertinent to this study as it attempts to differentiate informational messages from those expressing opinion or emotion (Verma et al., 2011). Situational awareness refers to people’s knowledge of the overall state of mass emergency events (Sarter & Woods, 1991). Situational awareness text contains more information to inform the state or decision-making during a mass emergency, whereas non-situational awareness text has more personal opinions, emotions, or status (Verma et al., 2011). For example, Lamb et al. applied a linguistic method to separate flu infection facts from emotional expression (mostly fear) for influenza surveillance on Twitter (Lamb et al., 2013). These studies explored what linguistic features could be used to identify situational awareness text and how well they could improve automatic detection (Lamb et al., 2013; Verma et al., 2011; Sen et al., 2015).

Given the existing scholarship, it appears difficult to apply emotion classification techniques to detect the presence of fear of crime in text. Moreover, the disclosure of the fear of crime involves human cognitive processes rather than pure emotion expression (Innes, 2004; Ferraro, 1995). Thus, it is essential to comprehend what linguistic traits can assist in detecting the presence of fear in online conversations about crime. Building upon related work that investigated human discourse patterns in the HCI community, we posed a second research question: What linguistic features are associated with the fear of crime in online conversations?

**DATA COLLECTION**

To gain insight into how individuals express their fear of crime in online discourses, we examined Reddit, a social media platform that enables users to join various communities, known as “subreddits,” based on shared interests or identities. Users can post and comment around particular subjects. One popular subject is crime.

Based on a quick search, users usually discuss crime in local subreddits (e.g., r/baltimore), crime-centric subreddits (e.g., r/crime), and support seeking & provision subreddits (e.g., r/Anxiety). Then, we browsed these conversations about crime. Crime-centric subreddits focus on the information on criminal investigations, which does not meet our research goal. Local subreddits and support seeking & provision subreddits focused on people’s experiences and opinions about crime in daily lives. However, the support seeking & provision subreddits contained limited conversations about crime. Thus, we chose local subreddits as the potential research site. Users in these local subreddits actively engage in discourses about local issues, including crime. We referred to a list that ranked the most popular city/local subreddits on Reddit by the number of subscribers and frequency of posts (Osiris32, 2016). Finally, we targeted the subreddit r/baltimore. The subreddit Baltimore was established in June 2008 and had approximately 47 thousand subscribers when we collected the dataset. Mass media and social media often portray Baltimore as an unsafe city with high levels of crime (Metzler, 2019). The image is echoed in r/baltimore, where users post numerous crime reports and engage in extensive conversations about crime.

To collect discourses about crime in r/baltimore, we consulted the FBI Uniform Crime Reporting (UCR) site (FBI, 2012), which delineates four violent crimes (i.e., murder and non-negligent manslaughter, rape, robbery, and aggravated assault) and four property crimes (i.e., burglary, larceny-theft, motor vehicle theft, and arson) in the United States. We meticulously examined the definitions of the eight types of crime and constructed a list of keywords. To acquire a comprehensive sample, we consulted a thesaurus (www.thesaurus.com/) and generated a wide range of synonyms for each initial keyword. We compared the synonyms’ meanings with the FBI UCR’s definitions. Then, we searched for the synonyms in r/baltimore and eliminated those that returned no search results. We added crime and criminal into the keyword list since users discussed crime without specifying the specific crime type. We also merged the crime types of larceny-theft and motor vehicle theft since they shared the same keywords (e.g., thief, theft, steal).

We developed a data crawler built upon the Python Reddit API Wrapper (PRAW) tool (praw.readthedocs.io/en/latest/index.html). PRAW enables researchers to access various back-end and often data-centric features on Reddit. The crawler collected all the posts and their comments that contained the keywords. After obtaining the initial dataset, we conducted a manual inspection for each keyword. The purpose was to ensure the posts and comments were related to violent or property crimes. For example, the keyword kill targeted posts that used kill for the meaning stop or fail, which had no connection to crime. Thus, we excluded these keywords from the list. The final list of keywords is presented in Table 1. We obtained 958 posts with 27,434 comments. The data collection was completed by October 2019. Among the 958 posts, there were 612 (64%) posts reposted from external websites, such as news or social media messages, and 346 (36%) original posts created by Reddit users. To
investigate the fear of crime in users’ discourses, we randomly sampled 2,000 comments from the entire dataset. Subsequently, our analyses were based on these 2,000 comments.

CLASSIFYING THE DISCLOSED FEAR OF CRIME ONLINE (RQ1)

To answer the first research question, what types of fear of crime are disclosed in online conversations, we conducted an iterative manual coding process (Corbin & Strauss, 1990) to identify the comments that disclosed the fear of crime. The two authors served as coders, both of whom are Reddit users and proficient in English.

First, we discussed the definitions of the fear of crime and randomly selected 100 comments. We coded them independently based on the understanding of definitions. While coding, we immersed ourselves in the context by reading the original posts and the backgrounds of crime incidents. The comments were coded into either FEAR comments (comments that disclosed the fear of crime) or NONFEAR comments (comments that did not reveal the fear of crime). Then, we discussed the coding results together. We found two distinct types of fear presented in these comments. One type of fear was an expression of worry about specific crime incidents experienced by individuals; the other type was an expression of diffuse anxiety around crime. Since the patterns of the two types of fear were different, we decided to further code FEAR comments into two subcategories: experienced (EXPC) and expressive (EXPV). We found that the two subcategories, EXPC and EXPV, could cover all circumstances for the FEAR comments.

Second, with the initial two-tier code schema, we coded another 400 comments. We calculated Cohen’s Kappa (Viera, Garrett, et al., 2005) to evaluate the inter-coder agreement. The coding result showed good agreement (.89) for the first-tier codes (FEAR/NONFEAR) and the second-tier codes (EXPC/EXPV) (.95). We discussed the disagreements. They mainly fell onto the comments where users talked about crime in general—the EXPV fear. Users did not always disclose the fearful emotion directly but used words such as “unsafe” and “high crime rates” to indicate a high probability of victimization. We decided to code this kind of comments into FEAR and then EXPV. We present the definitions and examples for the EXPC and EXPV fear comments in Table 2.

<table>
<thead>
<tr>

<tbody>
<tr>
<td>EXPC</td>
<td>An expression of worry about certain crime incidents that were or will be experienced by individuals.</td>
<td>One user shared a carjack incident happening to them and expressed a fearful emotion: I’m glad you at least got your car back. Well, I mean, it was completely totaled because the little shits decided that driving a 2009 Honda down a sidewalk was a good way to joyride, but hey. Geico paid me out! They also somehow didn’t hit any cars, just some trees, and curbs. The fun part was the kids didn’t know how to drive, so I was literally running down the sidewalk after them trying to flag someone else down. Was that a smart idea? Nah. <strong>But I was not in the best of mindsets after being jacked at 0430</strong> when I was walking to my car to go to work. One user was worried about being a carjack victim and took a precautious action: *I live in frigging <em>Columbia</em> and I wouldn’t leave the keys in my car.</td>
</tr>
</tbody>
</table>
One user expressed anxiety about more and more gun shoots in Baltimore; the user suggested the self-protection way: *Ops should be on every corner. Call in for federal support. The national guard should be here. It’s terrible to think about. The city is only getting worse. If u get caught with an illegal firearm, it should be attempted murder. Why else are u carrying a gun around? Protection? From who what have you done that you need a gun.*

One user presented a fear about a large number of homicide cases in different cities of the country: *Holy shit DC already has 13 homicides for the year. I don’t know Philly’s current count, but they had a record number of 351 last year. Maybe east coast cities are just going to keep getting more violent.*

</table>

Third, using the coding schema, the first author coded the remaining dataset (1,500 comments). Of the 2,000 comments, 105 were FEAR comments, and 1,895 were NONFEAR comments. The FEAR and NONFEAR comments’ distribution was imbalanced. Among the 105 FEAR comments, 38 were EXPV fear, and 67 were EXPV fear.

REGRESSION MODELS: THE LINGUISTIC FEATURES RELATED TO THE FEAR OF CRIME DISCLOSURE (RQ2)

Given that the disclosure of fear of crime involves human cognitive processes rather than being solely driven by pure emotional expression, emotion detection techniques encounter challenges in accurately detecting the presence of fear of crime, making them less suitable for this specific context. Therefore, we conducted a regression analysis to test which linguistic traits significantly predicted the presence of fear in online conversations about crime. First, we selected linguistic features based on previous literature and generated corresponding variables. Then, we constructed two logistic regression models.

Linguistic variable selection and measurement

The detection of fear of crime is a novel undertaking. Drawing on prior research that identified emotional and cognitive information in social media corpora, we selected linguistic features such as sentiment, emotion, self pronouns, named entities, and objectivity. Additionally, we incorporated non-linguistic features such as crime types and post sources to provide contextual information regarding the fear of crime. We explain the selection and manipulation of variables below.

Negative sentiment. Fear is a negative emotion (Ekman, 1992) and is associated with a negative sentiment in narratives or speeches (Schuff et al., 2017; Hoffmann, 2018). Sentiment analysis is generally considered simpler than emotion analysis in text classification tasks. Therefore, it is reasonable to use the negative sentiment feature to understand the fear of crime in public discourses. We applied the Vader toolkit in Python (Hutto & Gilbert, 2014), a widely-used sentiment analysis tool for social media text, to measure the negative sentiment in comments. The precision and recall scores of Vader for social media text were reported to be 0.99 and 0.94, respectively (Hutto & Gilbert, 2014). Vader provides four sentiment scores (namely “positive,” “negative,” “neutral” and “compound”). We chose the negative score as the negative sentiment variable in our study.

Anger. Plutchik argued that anger and fear were two complimentary emotions (Plutchik, 1980, 2001). However, research has not consistently demonstrated a negative correlation between the two emotions (Hoffmann, 2018). In our analysis, we observed that anger was often expressed in comments related to crime. People expressed their anger towards criminals or police misconduct. For example, one user commented, *I actually grew up in the city and learned that they were definitely my enemy. I saw them do legitimately horrible shit. I am glad to have moved away.*

Self and others. “Self” refers to words such as *I, me, I’d, I’m, my, etc.* “Others” refers to words such as *you, it, her, wife, kid, everyone, people, etc.* According to Pennebaker, the self pronouns (e.g., *I*) were used more by people who were “insecure, anxious, or depressed” (Pennebaker, 2011). We assumed that the “self” disclosure would be presented more in FEAR comments than in NONFEAR comments. Users also expressed their fear of crime when talking about crime incidents associated with their family and friends. To measure “self,” we adopted the “1st pers singular” (e.g., *I, me, mine*) and the “1st pers plural” category (e.g., *we, us, our*) in LIWC; to measure “others,” we used the “2nd person” (e.g., *you, your, thou*), “3rd pers singular” (e.g., *she, her, him*), “3rd pers plural” (e.g., *they, their, they’d*), “family,” and “friends” categories in LIWC. The variables were referred to as *I, we, you, shehe, they, family, and friend* respectively in this work.
Named entities. Named entities are elements of events and have been utilized for event detection (Edouard, 2016; Inyaem, Meesad, & Haruechayyasak, 2009). We observed that users discussed named entities related to criminals, crime times and locations, municipal police departments, and crime statistics. However, it is unclear which types of named entities were mentioned more frequently when the fear of crime was disclosed. Named entities can be identified by Named Entity Recognizer (NER) tools. According to the comparison result in (Atdağ & Labatut, 2013), Stanford NER (Finkel, Grenager, & Manning, 2005) demonstrated superior performance compared to other NER tools. We applied the seven-class model in Stanford NER, which can recognize location, person, organization, money, percent, date, and time. The output for each class was the frequency of named entities detected from the text.

Cognition. According to the “signal crimes” perspective (Innes, 2004), the fear of crime was perceived and disclosed by describing crime incidents (the “expression” stage), perceiving an actual or potential threat to them (the “content” stage), and generating appropriate emotional, cognitive, or behavioral reactions (the “effect” stage). The fear of crime was usually disclosed during the second and the third stage, which involved more human cognitive activities, such as estimation or inference, than the first stage. LIWC provides a “cognitive processes” category. The “cognitive processes” category represents various human cognitive activities, such as insight, causation, discrepancy, tentative, certainty, differentiation. In this study, we included this category, called cognition for brevity, and compared the variable in FEAR comments and NONFEAR comments.

Informality. Verma and Sen discovered that tweets containing situational awareness were more formal than those without, exhibiting comprehensive narratives and proper grammar (Verma et al., 2011; Sen et al., 2015). We hypothesized that discourse in FEAR comments would be more informal than in NONFEAR comments. To measure the degree of informality, we employed the “informal language” category in LIWC.

Objectivity. Objective and subjective linguistic features were used to detect situational awareness (Riloff & Wiebe, 2003; Wiebe & Riloff, 2005). Subjectivity was defined as linguistic expressions of opinions, evaluations, emotions, and speculations in (Banfield, 2014). If a sentence contains any expression of opinions, evaluations, emotions, and speculations, it is subjective; otherwise, it is objective. We assumed that more subjective discourses were presented in FEAR comments than in NONFEAR comments. We applied OpinionFinder (Wilson et al., 2005) to determine the objectivity of the text. The OpinionFinder lexicons had been applied to sentiment analysis for social media data (Verma et al., 2011; Díaz, Johnson, Lazar, Piper, & Gergle, 2018). Each comment was assigned as “objective” or “subjective” based on its overall objectivity. The objectivity variable was a dummy variable with “objective” equal to one and “subjective” equal to zero.

Crime types. The types of crime discussed in posts might be related to the fear disclosed in comments. Each post could include one or multiple types of crime. Based on our observation, violent crimes elicited more fear of crime than property crimes. We included seven specific crime types (i.e., assault, robbery, rape, murder, theft, burglary, arson) and the general variable crime as eight dummy variables, with a value of one indicating the post discussed the type of crime, and zero indicating the post did not.

Post source. The source of posts might be associated with the fear disclosed in comments. The original posts typically recounted the first-hand experiences of the poster with crime, while the external posts were usually sourced from news reports or social media. We included the post source feature as a dummy variable, with original posts equating to one and external posts equating to zero.

Table 3 presents the descriptive statistics for all variables for the three datasets: the entire dataset, the FEAR dataset, and the NONFEAR dataset.

Regression modeling results

In this section, we ran logistic regression models to examine which linguistic features in the FEAR dataset were distinct from those in the NONFEAR dataset and to interpret the results.

The dependent variable was coded as one for FEAR comments and zero for NONFEAR comments. Logistic regression was chosen due to the dichotomous nature of the dependent variable. While logistic regression does not have the same set of assumptions as a standard OLS regression (e.g., requires a normal distribution), it does assume that the independent variables are not excessively correlated, which we explain below.

As presented in Table 4, we included all the variables in Model 1; we excluded variables with p-values greater than 0.05 in Model 2. The Akaike Information Criterion (AIC) value for Model 2 (770) was lower than the AIC value for Model 1 (793), indicating that we obtained a more optimal model with fewer independent variables. If we continued to eliminate variables such as the insignificant variable *informality*, the AIC value would increase again. We conducted the likelihood ratio test to assess whether Model 2 significantly improved over Model 1 with fewer predictors. The result showed Model 2 was significantly better than Model 1 ($\chi^2 = 0.53$). We also checked multicollinearity for Model 2. All variance inflation factors were smaller than 2, indicating there was no multicollinearity issue.

Note: Significant at: *0.05, **0.01 and ***0.001 levels, respectively.

In Model 2, the most significant variables were negative (Z = 4.266, p < 0.001), objectivity (Z = -3.997, p < 0.001), and i (Z = 3.536, p < 0.001). Results for the three variables were consistent with our hypotheses.

Negative sentiment was positively related to FEAR comments, which echoed previous studies. Intuitively, the disclosure of fear of crime was more likely to be a negative sentiment. Given the negative sentiment detection task is mature, negative sentiment is a reliable indicator of fear of crime.

Objectivity was negatively related to FEAR, suggesting that FEAR comments were more subjective than NONFEAR. This was a strong predictor for distinguishing between FEAR and NONFEAR comments. FEAR comments were more likely to contain more subjective content, such as emotions and speculations, than NONFEAR comments.

The i pronoun is positively related to the FEAR comments. Users said i more in FEAR comments than in NONFEAR. By checking FEAR comments, the i scores of which were high, we found most of them were relating self-experiences of being victims or witnesses or being experiencing fear of crime. For example, one user shared personal experiences of being flattered, where many i pronouns were used: Yes, this happens to me as well. I will generally just laugh it off or act as if I did not hear them, then hurry on my way as fast as possible. I will then avoid that particular shop/area on the days that I know the employee is there (this information is often volunteered to me). I generally do not do well with confrontation.
Location and time in named entities were significantly related to the disclosure of fear of crime, meaning there were more location and time information in FEAR comments than in NONFEAR comments. For example, one user wrote an open letter to the Mayor of Baltimore where they described several crime incidents with specific location and time information and expressed their fear and willingness to move out of Baltimore: ... And then last night at 2 AM, a lifelong resident of Locust Point got shot outside our Royal Farms store. He was simply on his way home from work, and he was shot and killed because he had money. My chief safety concern used to be people breaking into my car to steal things, but last night even before this happened, I was worried when my wife was walking a mile to and from Cross St to meet a friend for drinks. This could have been her! ... Overnight, some thugs helped make that decision clearer for me. I love Baltimore, I love my Orioles, and I love the small town in a big city feel that Baltimore has - but I don’t want to lose my life for it.

The informality variable was negatively related to FEAR comments. The comments that expressed the fear of crime were more formal, while those that did not contain such fear were more informal. However, in Model 2, this was not a significant predictor ($Z = -1.836, p = 0.07$).

Variables for anger, others, cognition, crime types, and post source were not found to be significant in the regression models. We discuss these results in more detail in the Discussion section.

**DISCUSSION**

The present study sought to conceptualize the fear of crime in online discourses about crime through mixed methods. We reflect on some missing perspectives in existing definitions and called for further investigation to better understand, detect and mediate the fear of crime.

Recapping the conceptualization of the fear of crime

The fear of crime might be expressed implicitly without containing fear-related lexicons. In our manual coding, we identified only 105 out of 2,000 comments that displayed the fear of crime (RQ1). Many comments did not explicitly show emotion content. This finding aligns with existing work, where most respondents reported being unworried about crime (Gray, Jackson, & Farrall, 2010). One possibility is that, in conversations about crime, users tend to debate or provide support to others, rather than revealing private and personal status. Implicit expressions have been proven to be prevalent in critical self-disclosures (Chen, Lee, Li, & Huang, 2010; Lee, Chen, & Huang, 2010; Lee, Chen, Li, & Huang, 2010). When a fearful emotion is not explicitly expressed with emotion lexicons, tools have difficulty to detect the emotion and its cause (Ghazi et al., 2015). It is thus necessary to further investigate how to detect implicit fear of crime. Another explanation is that users may consider Reddit as an inappropriate platform to discuss their fears. In the support seeking & provision subreddits, we rarely found explicit fear disclosure. People’s willingness to engage in self-disclosure is influenced by the platform’s affordances and other users’ interactions (Yang et al., 2019). For example, Reddit users opted to utilize throwaway accounts when engaging in emotional self-disclosure to safeguard their identities (Mann & Carter, 2021). Platform design should consider incorporating features that enhance privacy and allow users to control the visibility of their identities, potentially fostering a more comfortable environment for emotional self-disclosure.

In our manual coding, we categorized the fear of crime into two types: expressive fear and experienced fear, which aligns with Gouseti’s classification for fear of crime (Gouseti, 2016). The results indicated that people were more likely to express expressive fear than experienced fear (RQ1). Expressive fear refers to an emotional reflection that is more diffuse and intangible than any specific event. Its intangible and diffuse nature allows individuals to articulate and share subjective emotional experiences without the need for specific triggers. In contrast, experienced fear may stem from specific traumatic events or personal encounters with crime, causing individuals to be more cautious or hesitant in disclosing those experiences. Overall, the difference in expression between expressive fear and experienced fear underscores the multifaceted nature of the fear of crime, highlighting the need to explore the underlying psychological and sociocultural factors that influence individuals’ preference for one type of fear expression over the other.

The regression model results suggest that negative sentiment, objective expression, and first-person personal pronouns can serve as indicators for identifying FEAR comments. These variables were more frequently used to describe the context of crime incidents and people’s emotional reactions to crime. The regression model also revealed the difficulty of capturing the cognitive processes associated with the fear of crime (RQ2). Cognition was a negative predictor ($Z = -1.715, p = 0.09$), suggesting that FEAR comments contained less cognitive content than NONFEAR comments. However, the disclosure of fear was often accompanied by cognitive processes. For example, a user might estimate the risk level in a potentially dangerous situation and express fear, as shown in this example: And what happens if I lose control of the gun and it’s turned on me or someone I love? Because that is quite likely. Getting a punch in the face is not nearly as bad as potentially getting shot - not to mention the alarming prospect of actually taking a life, regardless of whether that person deserves it or not. In another example, a user might express their opinion on crime: It’s a long shot, but maybe Steam has some record or info about the laptops.
That, of course, would assume that the robber wouldn’t just format the drive. But maybe they can see if it logs in at any point. Quite frightening. Good luck! The examples demonstrate the intertwining of cognitive processes with the disclosure of fear, indicating the need for further exploration and understanding of cognitive processes from different perspectives in the fear of crime. The “awareness of crime” concept (Gabriel & Greve, 2003) and the “signal crimes” perspective (Innes, 2004) provide frameworks to comprehend the cognitive dimension of the fear in people’s narratives. Both frameworks break down the disclosure of the fear of crime into multiple components. For instance, the “signal crimes” perspective treats a crime incident as a signal with three stages: interpreting crime incidents (“expression”), assessing actual or potential threats (“content”), and modifying behaviors (“effect”).

Furthermore, we should not view the fear of crime as entirely negative. It can serve as a reminder for people to take precautions and avoid becoming victims. Ferraro argued that a person might perceive a high likelihood of being a victim of crime without necessarily feeling fearful about it (Ferraro, 1995). Gray et al. argued that, unlike dysfunctional fear, functional fear of crime does not diminish the quality of life if people take precautions and feel safer (Gray et al., 2010). Therefore, functional fear is the desired state. Previous research suggests that higher crime levels may increase the fear of crime but do not affect feelings of insecurity (Visser et al., 2013). Additionally, Ferguson and Mindel (2007) found that factors such as social support, neighborhood satisfaction, and collective efficacy play a positive role in managing the fear of crime, while social distrust and perceived ethnic threat contribute to the induction of fear of crime (Visser et al., 2013). Considering that many conversations about crime and victimization occur in online communities, it is essential to develop a comprehensive understanding of how fear is manifested and communicated in different online contexts. Understanding the factors that influence the disclosure of the fear of crime, such as social support and collective efficacy, opens avenues for targeted interventions. Design considerations may include interactive features that foster social connections, encourage positive interactions, and promote trust-building among users, ultimately helping to reduce social distrust and mitigate the dysfunctional fear of crime.

Limitations and Future Work
This work has several limitations. The manual coding was based on prior literature and the researchers’ subjective judgment. As such, we were unable to ascertain the users’ underlying intentions behind their narratives. Future work could explore the richer cognitive dimensions behind the narratives by conducting interviews or survey studies.

Furthermore, given the size of the ground truth dataset, we did not differentiate between experienced and expressive fear in the regression models. Additionally, the study did not include all possible linguistic features that might be related to the fear of crime, such as the fear disclosed in the posts and users’ profile information. In the future, it would be interesting to explore why expressive fear was more prevalent than experienced fear, whether expressive fear was over-represented, and what precipitated it. Additionally, the two types of fear possess quite distinct characteristics. It is worth studying how the two kinds of fear affect people differently, e.g., whether they are beneficial or detrimental to people’s daily routines and well-being, and how to design different detections or interventions for the two fears.

Finally, misdetection of the fear of crime may have ethical implications. For instance, underestimating users’ fear may lead to missing precautionary action reminders and thus victimization of crime; biased detection may reinforce the stereotypical images of certain populations that are related to crime. Researchers must be mindful when applying the findings to detection tools or interventions. Future work could investigate what factors could result in functional fear or positively influence managing the fear of crime and develop interventions (e.g., chatbots) in online conversations. Further, online platform should consider create a more comfortable space for users to disclose their fear of crime, not only anger or debates.

CONCLUSION
Online discourses about crime have increased the public’s awareness of crime and, at the same time, allow researchers to understand how the public discusses and reacts to crime in their daily lives. This study tried to conceptualize the fear of crime disclosed in online conversations about crime and explored ways to detect it. The manual coding revealed two types of fear expressed by users: “experienced” and “expressive.” By analyzing linguistic features in the comments, we constructed logistic regression models to explore their relationship with the fear of crime. The work contributes to our understanding by identifying negative sentiment, objective expression, and personal pronouns as the most relevant variables associated with the fear of crime. Overall, the results suggest that the fear of crime bears more meanings than emotional reactions. This study sheds light on future work to further model the implicit expressions of fear and the cognitive process involved in the expressions.

ACKNOWLEDGMENTS
We express our gratitude to the Doctoral Students Awarded Summer Dissertation Fellowships at Syracuse University for their support. Additionally, we extend our sincere appreciation to the colleagues and reviewers for their invaluable feedback on our manuscript.

ABSTRACT

The citation of scientific papers is considered a simple and direct indicator of papers’ impact. This paper predicts papers’ citations through team-related variables, team composition, and team structure. Team composition includes team size, male/female dominance, academia/industry collaboration, unique race number, and unique country number. Team structures are made up of team power level and team power hierarchy. Team members’ previous citation number, H-index, previous collaborators, career age, and previous paper numbers are a proxy of team power. We calculated the mean value and Gini coefficient to represent team power level (the collective team capability) and team power hierarchy (the vertical difference of power distribution within a team). Taking 1,675,035 CS teams in the DBLP dataset, we trained the XGBoost model to predict high/low citation. Our model has reached 0.71 in AUC and 70.45% in accuracy rate. Utilizing Explainable AI method SHAP to evaluate features’ relative importance in predicting team citation categories, we found that team structure plays a more critical role than team composition in predicting team citation. High team power level, flat team power structure, diverse race background, large team, collaboration with industry, and male-dominated teams can bring higher team citations. Our project can provide insights into how to form the best scientific teams and maximize team impact from team composition and team structure.

INTRODUCTION

Citing behavior represents the credits to those scientific works with intellectual contributions (Merton, 1988). Yet some researchers argue that high citations do not mean disruptive innovation to the scientific community (Wu et al., 2019), and citations bring structural biases to minority groups, disparities across institutions and countries (Sugimoto, 2021). Despite these shortcomings, the citation count is still a crucial metric to evaluate the impact of scientific work, individual scientists, journals, and departments (Bornmann et al., 2008). For example, the low citation of papers will influence how people perceive their quality and thus reduce close reading (Teplitskiy et al., 2022). The citation of scientists’ work is closely related to their received awards number and appointed apartment ranking (Cole & Cole, 1967). The citation of a paper also quantifies the impact of a scientific team who collaborates to finish the publication. Given the citation of papers requires the accumulation of time, it is a valuable task to predict the long-term team impact shortly after the paper’s publication.

Scientific work is more team collaboration than individual endeavors (Wuchty et al., 2007). Division of labor requires everyone to specialize in specific areas to solve complex problems (Becker & Murphy, 1992). Previous research predicts paper citations from paper features, journal features, author features, early citation, and peer review (e.g., Li et al., 2019; Ruan et al., 2020). But, the literature shows poor research endeavors in predicting citation count regarding team-related features. The science of science research community mainly focuses on exploring and stressing individuals’ characteristics to influence team impact instead of taking all researchers in the team as a whole. Specifically, Li et al. (2019) measured the characteristics of first authors (e.g., the accumulated citations, H-index, publication number) in the author features but ignored the contributions of all other authors. Compared with the influence of an individual, the team structure of how members communicate (Woolley et al., 2010), share power (Xu et al., 2022a) and divide the work (Xu et al., 2022b) has a greater influence on team performance. Besides the characteristics of the first authors or corresponding authors, the team composition, such as team size (Wu et al., 2019), gender and race diversity (Hofsträ et al., 2020), country diversity (Wagner et al., 2019) of team members are also determinants of team success. In this project, we aim to predict team impact using team-related variables, team composition, and team structure. Teams in this project is represented by the list of authors of one published article because the authors of one publication have to work together as a team for one or two years to get this paper published. As to team composition, we consider team size, racial backgrounds, institutional backgrounds, academia/industry collaboration, and gender-dominated variables for all authors. Compared with team composition, team structure is widely applied in organizational behaviors (Greer et al., 2010) and sports (Halevy et al., 2012). Still, few are discussed in scientific teams (Xu et al., 2022). Team structure comprises team power level and team power hierarchy. Team power level means the collective ability of the whole team (Greer et al., 2011). Team power...
hierarchy implies the distribution of resources within the teams (Greer et al., 2018). It can be hierarchical (e.g., top-down management) or flat (all team members share similar power), influencing the communication, collaboration process, and performance. Team power can be measured using team members' previous citation number, H-index, previous collaborators, career age, and previous paper numbers. We can compute the average value and Gini coefficient to represent team power level and hierarchy.

Integrating prediction and explanation is essential when we study social problems to understand how and why the phenomenon happened (Hofman et al., 2021). The explanation can help us open the black box of machine learning models. Instead of pursuing high accuracy, we also need to know models' ethical implications and consequences (Wallach, 2018). For example, although a model has high accuracy, it might bring bias to disadvantaged people. However, the research on paper citation prediction lacks a combination of high prediction and robust explanation. There are two branches of study in predicting team citation. One branch focuses on achieving high prediction results but lacks a thorough analysis of how variables contribute to final results. The other branch highlights the interpretability of models but lacks high predictability of team performance. In this paper, we choose XGBoost (Chen & Guestrin, 2016) to help predict team impact measured by citations. By applying the Explainable AI method SHAP (Lundberg & Lee, 2017), we can quantify feature contribution to the citation count. Meanwhile, we can understand how team features influence each team locally and all teams globally through interpretability. Based on that, we can provide insights into team formation in the scientific context.

This paper uses explainable AI methods to understand team formation and team impact. This study addresses the above research gaps by taking Computer Science (CS) as a test field to predict team citation through team structure and composition variables. This paper is structured as the followings. Section 2 summarizes the related literature. Section 3 details the research methods. Section 4 describes the model comparisons and feature contribution. The last Section 5 concludes the study and points out future research directions.

RELATED WORK
Features in Citation Prediction
The literature mainly predicts paper citation based on five aspects of information: 1) paper content, 2) peer review, 3) journal, 4) early citation, and 5) authors. Firstly, the paper's content, such as title, abstract, keywords, topic, and references, is used to predict paper citation count (Fu & Aliferis, 2010; Hu et al., 2020; Jiang et al., 2021, Yan et al., 2011). For example, Hu et al. (2020) applied the LDA model to extract keywords from titles, abstracts, and author-defined keywords. They then measured these keywords popularity on google scholar, research gate, and google trend websites. They suggested that keywords popularity was an important indicator of citations. Also, when papers cite the most recent and relevant references in the subfield, they would attract more attention in the community (Roth et al., 2012). Secondly, peer review, as an evaluation of paper quality, Li et al. (2019) extracted the most similar peer review texts to abstracts and proposed a cross-review matching mechanism in order to get a comprehensive and relevant review representation. Thirdly, journal quality, like, the impact factor, is an important predictive feature for paper citation (Fu & Aliferis, 2010; Yan et al., 2011). Fourthly, early citations of papers can contribute to long-term citations (Newman, 2014). Researchers predict 5-year citations based on the first two years (Ruan et al., 2020). The final aspect of author information is the main element in predicting citation. Researchers select the first, most productive, and most influential authors to help predict the whole team's performance (Fu & Aliferis, 2010). Usually, researchers might use a mixture of this content-based and bibliographic information to predict paper impact jointly. This paper uses a unique perspective—team-related variables—to predict paper citation. We take all individuals in the paper as a team to predict team outcomes.

Team Composition and Structure
Team composition mainly highlights demographic-related variables influencing team performance, such as team size, gender, race, sector, and country. For example, by analyzing the team photo after finishing the game, Saveski et al. (2021) trained machines learning to judge whether the team escaped successfully from the maze. They found that large teams, gender diversity, race diversity, and older but fewer age differences can improve the chance of success. Team size plays an important role in team performance. Team size, as a parameter in a model for the self-assembly of creative teams, could determine team performance (Guimera et al., 2015). Large teams tend to receive more citations (Wuchty et al., 2007; Larivière et al., 2014). However, Wu et al. (2019) showed that innovation does not scale up with large teams. As to gender composition, researchers designed games to illustrate how the proportion of different gender influences the process of cooperation in lab experiments. They concluded that female-dominated teams are positively related to equal conversations (Woolley et al., 2008). This is because women have more social sensitivity compared with men in teams, which means they can sense how others think through nonverbal signals. This result is consistent with an experiment that requires students to finish a project paper in class (Berdahl & Anderson, 2005). They found that majority-female and balanced teams prefer equal communication and shared leadership over time, which could encourage everyone to participate in activities and contribute to teams. Freeman & Huang (2015) studied how race diversity influences team performance in the WOS dataset. They divided race into
eight categories and found that although scientists prefer to work with those who are similar to them in race, homophily can lead to lower citations and low-impact journals. Thus, they confirmed an assumption race diversity has positive effects on teams. Compared with the industry, universities dominate in paper publishing (Larivière et al., 2018). The collaboration between these two different sectors can bring more benefits for teams. For example, by analyzing the paper published by Canadian institutions from 1980 to 2005, Lebeau et al. (2008) confirmed that university-industry teams have more citations than pure university or industry teams. When authors from different countries are involved in teams, it can cause an additive citation effect (Hsiehchen & Hsieh, 2015). Wagner & Leydesdorff (2005) also proved that international collaboration could receive more citations for papers. Overall, the diversity of demography in teams can increase team citation.

The team structure is made up of team power level and team power hierarchy. The concept of team power level and team power hierarchy has been discussed in different contexts. In the organizational behavior field, Greer et al. (2010) regarded the positions in organizations as power and computed the average positions as team power level and standard deviation as team power hierarchy. In sports, Halevy et al. (2012) measured team power with NBA players' salaries. They all found that team structure is crucial to team conflicts, team coordination, and team ultimate performance. When people have brainstorming, negotiating, and puzzle games in experiments, a flat structure measured by equal speaking-turn distribution among team members can maximize collective intelligence (Woolley et al., 2010). In the scientific context, as long as more than one person works on a common project, team power dynamics will influence every step of collaboration, including defining topics, distributing labor of division, choosing methods, deciding journal targets, etc. A researcher's career age, previous citation, H-index, previous collaborators, productivity, function, and role can also be taken as the proxy of power since they represent prestige, resources, knowledge, and experience (Merton, 1973). Xu et al. (2022a) took the career age as the basis of power, where senior researchers have more rights in decision-making than junior researchers. By analyzing teams in Computer Science, Physics, Sociology, Library & Information Science, and Arts & Humanities, Xu et al. (2022a) calculated the mean value and Gini coefficient of team members' career age to represent the team power level and team power hierarchy. Finally, they found that a flat structure at different team power levels can have higher team citations. Similarly, Xu et al. (2022b) identified the leaders who conceived, designed, supervised, and wrote in publications through paper contributions and suggested that a flat structure with multiple leaders was better for team novelty and long-term impact than sole leadership. Although these team-related features have been proved important to performance, few science of science research considers them when predicting citation.

Methods in Citation Prediction
Predicting paper citations uses either traditional statistics models or advanced deep learning models. Yu et al. (2014) applied multiple linear stepwise regression models to analyze the correlation between paper features and citations in around 1,000 papers in the field of Information Science & Library Science. Similarly, Fu & Aliferis (2010) used SVMs and logistic regression models to predict whether medical papers exceeded a threshold value within ten years. These simple models are easily interpretable by understanding the coefficient of related variables. Ma et al. (2021) utilized deep learning models Bi-directional Long Short Term Memory (Bi-LSTM) to predict AI paper citations in the long term. Even though they found deep learning models outperform other baseline models and achieve higher accuracy, they did not interpret the outputs from the black box model. In the library, information and document field, Ruan et al. (2020) predicted papers' citations within five years through the BP neural network. To explain the relative importance of features, they trained different models when they dropped one feature but kept all other features (leave-one-out model) and then compared model differences. The drawback is authors do not consider the correlation between variables, and the model computation has low efficiency. Integrating prediction and explanation in modeling is a future direction since explanatory power can quantify how much we explain and reveal the limitation of our understanding of the social phenomenon (Hofman et al., 2021).

The combination of XGBoost and SHAP has been used in various contexts, such as marketing, health care, and traffic safety. By analyzing the product reviews on Amazon with XGboost and SHAP, Meng et al. (2020) found that the length of reviews contributes most to the headset review helpfulness while the frequency of product attributes is most helpful to the facial cleanser consumers. Yang (2020) trained the XGboost model to predict patients' recovery and modality. Compared with gender, time in the hospital, and the presence of chronic disease, Yang (2020) concluded that age is the most important factor in COVID-19 mortality prediction through SHAP and LIME value contributions. In accident safety, when inputting traffic, network, demographic, land use, and weather features into the XGBoost model, the speed difference before and after accidents is the key to traffic occurrence (Parša et al., 2020). The accuracy can achieve 99% in the Chicago metropolitan highway dataset. Ma et al. (2022) predicted the visibility of papers that are broadly mentioned and long-term disseminated on social media through literature-related features (authors, journal, paper) and social media-related features (user, tweets). They found that XGBoost algorithms performed best in predicting paper visibility and explained the contributions of each feature in disseminating through the SHAP method. Overall, the methods can achieve a balance between a high prediction rate
and high interpretability. But the explanation AI method has not been widely applied in predicting and understanding team citation.

**METHODOLOGY**

**Data**

We use the DBLP dataset (https://dblp.org/), including 4,894,081 papers in the Computer Science (CS) field. We choose 3,658,127 papers that have more than one author from 1980 to 2020 since we assume a team must have at least two authors. We take authors in each paper as an independent team who collaborate together to finish a research project and publish the outcomes. For example, if a paper has five authors, then these five authors are considered to be a team. When we identify the gender and academia/company information of each author, there are unknown categories. Unknown gender-dominated teams occupy 27% (984,912) and unknown race teams occupy 36% (1,316,527). We exclude these unknown teams, and 1,675,035 teams are left with complete information.

**Measures**

**Team impact:** We use the 5-year citation to evaluate the impact of a paper, which is also the impact of a team who published this paper. This is a binary variable, high team impact (above or equal to mean value) and low team impact (below mean value). The mean 5-year citation is 5. 1,263,162 teams are below the mean value, whereas 411,873 teams are above the mean value. Above-mean value is labeled as 1, and the below-mean value is labeled as 0. Here, we do not use the median value of a 5-year citation as a threshold. The median value of a 5-year citation is 2 since most of the papers (63%) do not have more than two citations. Using the median value cannot show the distinct difference between high-impact papers and low-impact papers.

**Team size:** We count the number of authors in a team as the size of this team. The median team size value is 3.

**Gender:** Teams are assigned to male-dominated, female-dominated, and equal. For instance, male-dominated means the identified male author number is larger than the identified female author number. We use the Bert-based model trained by Acuna & Liang (2021) to predict authors' gender information. After excluding unknown categories, there are 1,316,193 (79%) male-dominated teams, 184,608 (11%) equal teams and 174,234 (10%) female-dominated teams.

**Race:** We calculate the team's unique number of authors' race. Acuna & Liang (2021) distinguished four kinds of race: Black, Hispanic, White, and Asian. The median value of unique race in teams is 1, suggesting that most of the teams are homogenous in race.

**Sector:** Teams are divided into pure academia, pure company, and combined. Pure academia (company) means teams are made up of all researchers from academia (industry) institutions, whereas combined teams have both academia and industry researchers. Manjunath et al. (2021) methods have been applied to match authors' institutions with eight categories in the Global Research Identifier Database (GRID), including government, education, company, facility, healthcare, nonprofit, archive, and others. We merge the health care (mainly universities) and education into academia and keep the company as the industry category. After excluding unknown categories, there are 1,501,131 (90%) academia teams, 63,399 (4%) industry teams, and 110,505 (7%) combined teams. Academia teams are dominating in paper publishing.

**Country:** We calculate the unique number of authors' countries based on authors' affiliations in a team. The mean value of a unique country in teams is 1, indicating that most teams come from the same country.

**Career Age:** We calculate the mean career age and Gini index of career age among all team members. The median value of mean career age is 8, and the Gini career age is 0.34.

**Citation:** We calculate the mean citation and Gini index of citation among all team members before collaborating on the paper. The median value of mean citation is 63, and the Gini career age is 0.50.

**H-index:** We calculate the mean H-index and Gini index of the H-index among all team members. H-index can comprehensively reflect a researcher's productivity and impact (Hirsch, 2005). The median value of the mean H-index is 3, and the Gini H-index is 0.50.

**Collaborators:** We calculate the mean collaborators and Gini index of collaborators among all team members before collaborating on the focal paper. The median value of the mean collaborator is 19.5, and the Gini coefficient of collaborators is 0.39.

**Productivity:** We calculate the mean papers and Gini index of papers among all team members before collaborating on the focal paper. The median value of mean career age is 15.25, and the Gini career age is 0.50.
Methods
An XGBoost model is trained for binary classification of high/low team impact. XGBoost applies a gradient tree boosting algorithm and has state-of-the-art classification performance (Chen & Guestrin, 2016). Firstly, we plan to use Python xgboost package. 80% dataset was taken as training, and the remaining 20% dataset was taken as testing. For the predicted value, the result is not balanced. Below-mean values have a more significant proportion. Thus, we take the up-sampling methods to ensure the trained dataset is balanced. We randomly choose from the positive values multiple times to make the positive instances number the same as the negative ones. Secondly, we evaluate the model's performance in comparison with baselines. Thirdly, SHAP is an explainable AI method used for model interpretation through Shapley value (Lundberg & Lee, 2017). By comparing the difference with the variable and without the variable in the model, the importance of each variable can be inferred. SHAP interprets the contribution values of each feature in each instance to the particular prediction. We can draw the relative feature importance of explanatory variables on the model results using the mean SHAP value of variables and the distribution of the SHAP value of variables for each individual. Finally, we draw interactive plots to show the relationship between variables and SHAP values.

Evaluation Metrics
The results of the predicted model can be divided into four categories: True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN). Here 0.5 is used to be a threshold in the 2-binary classification where the instance with value larger than 0.5 is a positive one, and the instance with a value lower than 0.5 is a negative one. We calculate the accuracy (ACC) as the evaluation metrics: \( \text{ACC} = \frac{(TP+TN)}{(TP+FP+TN+FN)} \). F1 measure combines the consideration of Precision, \( \text{Precision} = \frac{TP}{(TP+FP)} \), and Recall rate, \( \text{Recall} = \frac{TP}{(TP+FN)} \), \( \text{F1} = \frac{(\text{Recall}*\text{Precision}*2)}{\text{Recall}+\text{Precision}} \). Difference from using 0.5 as threshold values, AUC considers the performance of different thresholds. AUC considers the variables of Recall, and False Positive Rate, \( \text{FPR} = \frac{FP}{(FP+TN)} \). The larger the AUC, the better the model’s performance is. The range of AUC is 0-1.

Hyper-Parameter Tuning
In the XGBoost model, we set the learning rate is 0.01, the subsample ratio of the training instances is 0.8, the maximum depth of a tree is 20, the minimum sum of instance weight in a child is 5, the minimum loss reduction required to make a further partition on a leaf node of the tree is 3. Fig 1 shows the results of Train and Test within 100 epochs. Our objective of the model is to maximize the AUC and Error (1-ACC) value. It suggests that the changes in error and AUC values in the test dataset have been stable. Thus, we choose the last epoch as the best performance of our model.

RESULT
Comparison of Model Performance
We choose logistic regression and decision tree as our baseline models. We can conclude that the XGBoost model outperforms these traditional models in all three evaluation metrics: ACC, F1, and AUC. Although the XGBoost model only has a 4% higher accuracy rate than the logistic model, we need to consider that our sample is large, so the 4% improvement means a large sample.

Results of Feature Contribution
When we choose to predict models, we can feed more features into the model to increase the prediction performance. When we explain how variables contribute to prediction performance, we need to consider the interdependency between features, especially the team structure variables, such as career age, H-index, productivity, citation, and collaborator. These team structure variables are highly related (Table 2-3). We can find that the H-index is highly related to career age, productivity, citation, and collaborator, in the combination of mean value and Gini coefficient. Thus, when we try to explain the feature contribution, we only consider H-index in the team structure.

Table 3. Pearson correlations between gini team structure variables

Cases
We visualize two cases (Fig 2) to show how features contribute to each team locally. Comparing the first team with the second one, we can find that lower Gini H-index, higher Mean H-index, and larger team size positively contribute to team citation.
We apply the SHAP method (Lundberg & Lee, 2017) to better interpret the XGBoost model's results. This method measures the contribution of each feature to each team in the DBLP dataset and then aggregates the results of all samples. The aggregated mean (SHAP value) are ranked from high to low. In Fig 3, team power level (Mean H-index) and team power hierarchy (Gini H-index) are the critical factors, followed by Race Number, Team Size, Academia/Industry, Male/Female, and Country Number. The mean H-index of the whole team members stands out in the first position, and meanwhile, the distribution of the H-index within the whole team is important. We can conclude that team structure variables are more important than team composition variables.

In Fig 4, each point represents the specific contribution value of each feature in each individual. The x-axis means the impact of each feature on the team's performance in citations, positive or negative. The color of each point implies the scale of the feature value (red is highest, blue is lowest). Firstly, as to the Mean H-index, the higher the mean H-index is, the more positive impact it has on team citation. When the Gini coefficient is low in H-index, which suggests that everyone shares a similar H-index, the team has a higher probability of having above-mean citations. When teams are more diverse in race, they have more citations. When the team size is larger, teams have more influence. Most of the combined teams (mixed color) and industry teams (pure red) are on the left side, whereas academia teams (pure blue) are on the right side. It shows that combined teams and industry teams outperform pure academia teams. Female-dominated teams (pure red), and equal teams (mixed color), which are mainly on the left, indicate that female-dominated teams and equal teams have fewer citations than male-dominated teams (pure blue). Finally, when teams are diverse in the country, they might have more citations or fewer citations. It suggests that country diversity can bring innovation but also bring cultural barriers.
Interactive Feature Contribution

We draw the dependence plots between any two variable pairs and found an interactive effect between team power hierarchy (Gini H-index) and team power level (Mean H-index) in Fig 5. Each dot is a team. The x-axis is the value of Gini H-index, whereas the y-axis is the SHAP value for the feature, which represents how much the feature's value changes the output of the model in prediction. The color bar represents a second feature Mean H-index. The blue points (low Mean H-index) are higher than red points (high Mean H-index) when the Gini H-index increases (Fig 5). When teams have a high hierarchy, teams with low team power levels are more likely to have a higher impact than teams with high team power levels (Fig 5). It suggests that teams with low team power level benefits more from a hierarchical structure than teams with high team power level.

CONCLUSION

This paper calculates different team composition and team structure variables to predict high/low team citation impact with the XGBoost model. Our model outperforms traditional models, such as the logistic model and random tree, in terms of ACC, F1, and AUC metrics. Then, we apply the Explainable AI SHAP method to interpret each feature contribution to each team's citation prediction. After aggregating all individual values, we found that team structure is more important than team composition. The team power level and hierarchy rank first and second in the overall contribution, followed by unique race number, team size, male/female dominance, academia/industry collaboration, and unique country number. High team power level is positively related to team citation, whereas high team power hierarchy is negatively related to team citation. There is an interactive effect between team power level and hierarchy. When team members are more diverse in race, are more in team scale, and have academia/industry interaction, they can receive more citations. But including female collaborators can reduce citations. It might be caused by the specific CS discipline where female researchers are underrepresented. The diversity in institutional countries cannot guarantee an increase in citations.

Our project makes important contributions to team citation prediction from team composition and structure. We enrich team-related variables rather than emphasize individual superstars to predict citation impact. The ranking of feature prediction through SHAP values can offer suggestions to scientific teams about the priority lists when they try to form new teams and build connections to maximize team performance. However, we need to admit that the
team-related variables we choose have limitations. On the one hand, variables about mean career age, mean productivity, mean citation and mean collaborations and mean H-index have an overlap to some extent. On the other hand, the variables we choose are not complete. We could still consider the team composition from the department dimension. Or we could consider whether teams belong to high-rank institutions. Secondly, our model is trained to predict whether team citation is above the mean value or not. The best model, XGBoost, can only reach 70% accuracy. The prediction results still have gaps with previous literature. Finally, we only test our results in the CS field. For the future work, there are interesting areas of extending this research to different disciplines including science, social science, and humanities. It is great to use two Explainable AI methods to cross validate the feature importance.

Social VR: A Promising Platform for Enhancing Mental Wellness among College Students

You, Xinyue (Sally)  The University of Texas at Austin, USA | xinyueyou23@utexas.edu

ABSTRACT
In recent decades, there has been an alarming increase in the number of university and college students struggling with intensifying psychological distress, which has become a mental health crisis on campuses. To address this issue, this study proposes social VR as a potential platform to promote social interaction and improve mental well-being for college students. In this study, 68 students explored a variety of social VR applications in a classroom setting. Results showed that a) virtual space, audio, avatar, communication types, and activities were key contributing features that facilitated social interaction among college students in social VR and have the potential to enhance mental wellness, and b) the anonymous nature, communicative cues, and designated private areas provided by social VR platforms were effective in facilitating self-disclosure, indicating social VR’s potential in delivering mental health services such as individual and group counseling and therapy. This study provides evidence that social VR can enhance social interaction and communication while serving as a platform for professional mental health care, a venue that has yet to be explored in previous studies.

KEYWORDS
Virtual reality; social VR; mental health; virtual interaction; virtual worlds

INTRODUCTION
In recent years, there has been a growing concern over the mental health of college and university students, given the increasing number of students reporting mental health issues. According to the American College Health Association, the percentage of college students being treated for at least one mental disorder has risen from 18% in 2005 to 43% in 2022, with depression and anxiety being the most commonly reported issues (American College Health Association, 2022). What’s more, 77% of students reported moderate or high levels of distress, and 51.7% reported feelings of loneliness (American College Health Association, 2023).

To address this rising demand for psychological care, educational institutions have increased their investment in campus mental health services (Legislative Analyst’s Office, 2021). Despite these efforts, many institutions still struggle to meet the increasing demand (Xiao et al., 2017). With limited resources and the ongoing rise in mental health concerns among college and university students, it has become necessary to find supplementary tools and platforms that provide effective mental health care.

The emergence of digital technology has had a significant impact on all aspects of people’s lives, including the way individuals connect with each other. With the internet removing the burden of physical distance, online communities allow users to connect with their existing friends and make new connections with like-minded individuals, thereby expanding the scope and reach of their social support networks (Smith-Merry et al., 2019). These online communities also offer a level of anonymity and reduced social pressure, which enables individuals to share their experiences and emotions more openly. This facilitates a sense of belonging and social support, which can promote mental health and psychological well-being (Lattie et al., 2019).

As a unique type of computer-mediated communication channel, social VR platforms provide “3D virtual spaces where multiple users can interact with one another through VR head-mounted displays” (Maloney & Freeman, 2020, p. 510). With the offering of advanced verbal and non-verbal expression capabilities and diverse social activities, social VR platforms facilitate vivid spatial, temporal, emotional, and social experiences that are similar to face-to-face interactions (Maloney & Freeman, 2020; Maloney et al., 2020b; Sykownik et al., 2021; Zamanifard & Freeman, 2019). This natural and effective way of building social connections has made social VR increasingly popular, especially during the COVID-19 pandemic, where social contact has become highly sought after (Kelley, 2021; Sykownik et al., 2021). For instance, Rec Room, one of the social VR platforms, saw a threefold increase in active users during the 2021 holiday season compared to the same period in 2020 (Lang, 2022). Social VR’s growing popularity has prompted researchers to investigate the social practices and phenomena that take place in these emerging social spaces (Ahn et al., 2021; Kirchner & Forsberg, 2021; Maloney & Freeman, 2020; McVeigh-Schultz, 2018).

However, previous research reveals three limitations. First, while social VR platforms are accessible through multiple devices, such as desktops and smartphones, most academic studies have closely linked social VR with its VR component. Existing studies either limited their sample to users who access social VR through VR headsets (Maloney et al., 2021; Moustafa & Steed, 2018) or did not specify the devices used (Maloney & Freeman, 2020; Maloney et al., 2020a). Therefore, more research is needed to investigate the device types users use to access social
VR and whether these device types affect user interactions. Second, previous studies focusing on specific populations’ experience in social VR have shown that users in different age groups and types of relationships differ in their perceptions and experiences in social VR (Acena & Freeman, 2021; Maloney et al., 2020a; Maloney et al., 2021; Zamanifard & Freeman, 2019). Therefore, more input from college students is needed regarding how they perceive the design of social VR in terms of promoting social interaction with their classmates. Third, although research has focused on the diverse activities provided by social VR platforms, there is a lack of studies that connect the social aspect of these platforms to potential mental health benefits. Hence, further research is necessary to explore the potential of social VR platforms in providing mental health care and enhancing mental well-being. This paper aims to address the limitations mentioned above by investigating two research questions among college students who access social VR platforms through their preferred devices: 1) identifying the specific features of social VR platforms that enhance college students’ social experience; and 2) evaluating social VR’s potential as a platform for mental health care.

This paper contributes to the existing literature in three ways: 1) expanding the understanding of social interaction and communication in social VR platforms; 2) enriching the knowledge of social VR platforms’ impact on college students’ social experience by identifying specific features that foster social interaction; and 3) examining the potential of social VR to provide mental health services.

LITERATURE REVIEW SOCIAL RELATIONSHIPS TO MENTAL WELL-BEING
Social relationships play a critical role in human survival and are closely linked to achieving and maintaining good health and well-being (Haslam et al., 2015). Extensive research has established that positive and supportive social connections can enhance mental health and well-being, while the absence of social connections can have adverse effects on individual’s physical and mental health across all age groups (Asante & Karikari, 2022; Clark et al., 2018; McLouglin et al., 2018; Nabi et al., 2013; Newman & Zainal, 2020).

Social support and social connectedness are the two major concepts relevant to social relationships, and are frequently identified as mechanisms for enhancing health and well-being (Haslam et al., 2015). By definition, social support refers to one’s perception or experience of being cared for, esteemed, valued, and loved by others, as well as being a part of a social network where mutual assistance and obligations are present (Wills, 1991). It can be further categorized into different forms, such as informational support (e.g., resources and coping strategies), instrumental support (e.g., tangible assistance and specific aids), and emotional support (e.g., warmth and reassurance) (Taylor, 2011). Beyond these specific forms, social support, as the definition suggests, also encompasses the perception that such support is available and can be received when needed (Wills, 1991). Research has shown that perceived social support can trigger feelings of support, reduce levels of anxiety and depression, and enhance mental wellness (Nabi et al., 2013; Taylor, 2011; van Brakel et al., 2023).

Social connectedness, on the other hand, reflects the sense of belonging and attachment to a social network, and is characterized by the “subjective awareness of being in a social world” (Lee & Robbins, 1995, p.338). While social support involves the provision of assistance and emotional comfort from others, social connectedness is more focused on the sense of being part of a larger social network. The two concepts are interrelated, as social connectedness can be fostered through the continuous provision of social support. Research has shown that social connectedness is associated with higher levels of resilience and more positive mental health outcomes (McLouglin et al., 2018). Therefore, building and maintaining social connections can promote both social support and social connectedness, leading to positive effects on mental health and well-being.

COMMUNICATION CHANNELS FOR SOCIAL CONNECTION BUILDING
The way people build social connections has evolved significantly with the rise of internet-based technologies. While in-person interaction used to be the primary means of building social support and connectedness, a growing number of individuals now rely on computer-mediated communication to interact and connect with others. By engaging in online forums, gaming, and social media platforms, people can access large communities of individuals with diverse backgrounds and experiences that may not be available in their offline network, enabling them to build social connections that might be lacking in their daily lives (Smith-Merry et al., 2019; Walther & Boyd, 2002). Furthermore, online applications provide real-time messaging, making it easier for the maintenance of distant relationships. The anonymous nature of online communication also promotes a sense of freedom and reduces social inhibition, encouraging individuals to express themselves more honestly and openly, as well as a sense of privacy and protection, providing a safe space for the discussion of sensitive or personal topics (Baccon et al., 2019; Fox & McEwan, 2017; van Brakel et al., 2023).

Despite the many benefits of online communication channels, computer-mediated communication is still perceived as limiting when compared to face-to-face interaction due to the lack of social cues. In-person communication allows individuals to pick up on nonverbal cues, such as facial expressions and body language, which are lost in audio or text-based communication. Videoconferencing platforms, though providing nonverbal cues, require people
to maintain close-up eye gaze for extended periods, making communication less natural and more tiring than
in-person interaction (Bailenson, 2021).

Numerous studies conducted during the COVID-19 pandemic, when in-person interaction was restricted due to
social distancing, have reported on these setbacks of computer-mediated communication. For example, one study
investigated the relationship between different modes of computer-mediated communication and well-being during
the pandemic and revealed that text-based communication had a negative association with well-being, while face-to-
face interaction had a positive association despite the health threats (Newson et al., 2021). Although this study did not
find an association between well-being and video-based communication, another study suggested that extended
use of videoconferencing could lead to issues such as excessive close-up eye gaze, cognitive overload of processing
nonverbal cues, increased self-awareness and performance pressure, and lack of physical mobility, resulting in
feelings of exhaustion and stress, commonly known as “Zoom fatigue” (Bailenson, 2021). These studies indicate
that face-to-face interaction is crucial for maintaining good mental health, yet traditional digital technologies cannot
fully replicate such experience, and may even cause negative consequences when used excessively.

SOCIAL VR TO ENHANCE SOCIAL CONNECTION

Social VR platforms, unlike traditional computer-mediated communication channels such as social networking sites
and videoconferencing applications, offer a variety of experiences comparable to face-to-face interactions through
the incorporation of multiple modes of communication and diverse activities designed to facilitate social interaction
among users (Handley et al., 2022). As a type of social virtual worlds, social VR platforms are housed within 3D
computer-generated environments (Spanlang et al., 2014), and allow users, embodied in their digital representations,
also known as “avatars”, to interact with others synchronously in a way that closely resembles the way they interact
in the real world (Bailey & Bailenson, 2015). Additionally, social VR platforms provide users with great
imaginative freedom to generate their own content, such as customizing their avatars, creating thematic virtual
spaces, and launching events and activities of their interests (Acena & Freeman, 2021; Barreda-Angeles &
Hartmann, 2022; McVeigh-Schultz et al., 2019).

Social VR differentiates from other social virtual worlds in that it is primarily accessed using a head-mounted
display. This device provides users with a high level of immersion and realism in their virtual experience by
blocking out the perception of real-world surroundings, responding naturally to users’ actions, and transmitting
sensory feedback including visual, haptic, auditory, and olfactory cues (Bailey & Bailenson, 2015; Barreda-Angeles
& Hartmann, 2022; Markowitz & Bailenson, 2019). This immersive nature allows users to feel fully embodied and
physically located in the virtual environment, and interact with virtual objects and avatars of other users in a very
intuitive way, much like in the real world (Barreda-Angeles & Hartmann, 2022). Given the close resemblance to
face-to-face interaction, social VR platforms may overcome the limitations of other computer-mediated
communication channels, facilitating social interaction that is as beneficial to mental health as in-person interaction.

A growing body of research has provided evidence in support of this statement. For example, a quantitative survey
conducted among 1231 social VR users found that the heightened sense of presence, facilitated by social VR
platforms, leads to increased perceived social support, which in turn, positively affects the perceptions of overall
social support and subjective well-being (van Brackel et al., 2023). Similarly, a qualitative study focused on the
experiences of LGBTQ users highlighted several key benefits of social VR: 1) social VR facilitated natural and
immersive social interaction that closely resembled face-to-face communication; 2) social VR engaged users in
multi-modal communication, fostering more open and inclusive interaction within the LGBTQ community; and 3)
social VR constitutes a safe space for LGBTQ users to build close relationships, which would be beneficial for their
social lives beyond the virtual environment (Acena & Freeman, 2021).

In light of these findings, scholars have delved into specific features of social VR applications that promote social
interaction. Based on an analysis of 44 commercial and prototypical VR applications, Handley and colleagues
(2022) developed a taxonomy of design choices that classified features into three distinct categories. The "self"
category covers all aspects of avatar embodiment, including avatar representation, customization, manipulation, and
locomotion. The "interaction with others" category is focused on communication modalities, such as verbal and
nonverbal communication, user blocking and muting, as well as activities that facilitate social interaction. The
"environment" category includes design choices concerning the virtual space’s construction, manipulation, and
openness.

Several studies have utilized the generalized taxonomy to investigate the impact of design choices on user
interaction and experience in social VR (Freeman et al., 2020; Maloney & Freeman, 2020; Maloney et al., 2020a;
Maloney et al., 2020b; Sykownik et al., 2021; Zamanifard & Freeman, 2019). One study focused on couples’
experiences of using social VR to maintain their long-distance relationships and found that avatars played a crucial
role in enhancing intimate interaction between couples, as embodied physical contacts made them feel together
despite being physically apart (Zamanifard & Freeman, 2019). In another study, nonverbal communication was
identified as an essential facilitator of interaction in social VR, perceived as more effective and flexible in conveying social meanings than other communication channels. The study also noted that the variety of communication modalities, both verbal and nonverbal, contributed to an enhanced sense of connectedness (Maloney et al., 2020b). Existing literature has explored the efficacy of social VR in enhancing social interaction among individuals in various relationships and settings, such as long-distance relationships (Maloney & Freeman, 2020; Zamanifard & Freeman, 2019), colleagues (Kirchner & Forsberg, 2021), and in-group members (Acena & Freeman, 2021). However, little research has focused on college students’ experiences of building connections in social VR. One study involved 12 master’s students exploring social, educational, or entertainment VR applications across six weeks, and found that interaction in social VR enhanced the sense of connectedness and provided a better learning experience (McGivney et al., 2022). However, it was unclear which specific feature(s) of the VR applications attributed more importance to social interaction. The other study, conducted among 81 college students in a class setting, showed that avatar appearance had an effect on students’ sense of presence and perception in social VR, and their group dynamic and sense of connectedness increased over time. This study shed light on the role that avatars played in students’ experience in social VR, yet its quantitative perspective lacked details about how students connected and interacted with each other in social VR and the role that their avatars played in the process.

Given the high level of technological comfort among college students, and their struggles with increasing mental health issues (Lattie et al., 2019), they are most likely to benefit from social VR. Therefore, this study aims to enrich the understanding of college students’ experience in social VR, identify feature(s) of social VR platforms that promote interaction, and assess the potential of social VR to improve students’ mental well-being.

METHOD PARTICIPANTS
The current study drew data from a sample of 68 undergraduate and graduate students who 1) were enrolled in a course that included VR experiences and 2) had consented to share their data. Students were introduced to a variety of social VR applications during the course and spent time exploring and learning in the virtual space. As part of their grade, all students were required to complete a survey following each virtual reality experience. As a result, the 68 participating students generated a total of 224 data entries.

Thirty-two of the 68 participants provided demographic information. Gender was distributed evenly, with 16 males, 15 females, and one student who preferred not to self-identify. Participants are 25 years old on average (\(SD = 7.97\)), with the youngest being 20 and the oldest being 54 years old. According to the data, 13 participants identified as Asian or Asian-American, 12 as White, 4 as multiracial, and one as African, African-American or Black, Hispanic or Latinx, or Middle Eastern. In terms of prior VR experience, 21\% (\(n = 14\)) had never used VR before the course, 26\% (\(n = 18\)) had used VR before, and 53\% (\(n = 36\)) did not report this information.

MATERIALS
The current study drew data from a sample of 68 undergraduate and graduate students who 1) were enrolled in a course that included VR experiences and 2) had consented to share their data. Students were introduced to a variety of social VR applications during the course and spent time exploring and learning in the virtual space. As part of their grade, all students were required to complete a survey following each virtual reality experience. As a result, the 68 participating students generated a total of 224 data entries.

Description of the course
This study was part of a large-scale collaborative research project aimed at examining how students learn and interact in social VR platforms. The project was led by faculty members teaching VR-related courses at four institutions across the United States. The courses varied in their specific focus and structure, but all included virtual experiences as a key component, giving students direct experience with the technology and enabling them to put their learned concepts into practice. During each session, students participated in social VR visits chosen by the course instructor (see Table 1 for social VR platforms descriptions) and completed tasks assigned by the instructor. These tasks could involve independent exploration, forming project teams, conducting group meetings, virtual field trips, guest lectures, or presenting research posters. A videoconference was kept open throughout the VR sessions, with teaching assistants available to resolve technical issues.

Device Usage
In the social VR platforms, students employed a range of digital technologies to connect and interact with others, including desktop/laptop, VR headset, smartphone/tablet, and others (see Table 2). Desktops/laptops were used at least once by 84\% of the participants (\(n = 57\)), while 60\% used VR headsets at least once (\(n = 41\)). The most frequently used VR headsets included the Oculus Quest, Oculus Go, Oculus Rift, and HTC Vive. During multiple sessions, 51\% of the students (\(n = 35\)) utilized different devices, with 47\% (\(n = 32\)) alternating between desktops/laptops and VR headsets. The total sessions completed by students varied based on different courses’ requirements, ranging from one to six sessions (\(M = 3, SD = 1.59\)).
Analysis
The study employed thematic analysis following Braun and Clark's guidelines (2006). Initially, the author read through the students' responses with the research questions in mind to gain familiarity with the data. In the second round of reading, the author highlighted important pieces of data and noted down emerging ideas, which served as the basis for the initial list of codes. The author then grouped the notes and preliminary codes into meaningful categories and created a codebook that defined, labeled, and established criteria for each code. In the third round of reading, the author used the codebook to systematically code each response. During this process, the author identified new codes and refined code definitions as necessary. Once the codebook was finalized, the author completed coding all the responses. Finally, the author analyzed the codes to identify overarching themes and patterns, which were used to develop a rich description of students' social experiences in social VR.

RESULTS
During the courses, students had the opportunity to explore different virtual worlds, each with unique features and settings. This exposure allowed them to gain valuable insights into design choices that foster social interaction within virtual environments. Additionally, students' reflections on their virtual reality experiences indicated that social VR platforms have the potential to improve mental well-being. In this section, the findings will be presented in two parts: the first part will discuss the design choices that participants found beneficial for developing social connections, while the second part will identify aspects that could make social VR an ideal platform for enhancing mental wellness and providing mental support.

SOCIAL INTERACTION MADE EASY: KEY FEATURES IN SOCIAL VR PLATFORMS
The immersive, engaging, and inclusive environment affords user interaction
As the main area where users immerse and interact with others, the virtual space plays a significant role in the crafting of user experience and building of social connections. According to P49 (desktop), “The virtual world was very much designed to facilitate conversation, and created various spaces and opportunities for people to interact in different active and passive environments.”

Others echoed this view. They praised the virtual environment for providing the space for them to explore and interact with others, creating a shared experience and promoting the feeling of social connection: “The virtual rooms felt very immersive and the way you were able to walk through them and interact was absorbing.” (P18, VR headset); “The lab environment for which the speaker gave us a tour was very engaging and afforded different users to interact and connect. We could stroll from different parts of the environment and interact with each other efficiently.” (P35, desktop); “The virtual world was helpful via the interesting environments that were able to be explored with the people around you.” (P64, VR headset) As participants mentioned, the virtual environment felt very “immersive”, “engaging”, and “interesting”, it attracted users to “walk through” the environment with others, and this was why they felt the virtual space helped facilitate social interaction.

Participants went beyond evaluating the virtual environment as a whole and reflected on specific aspects that contributed to an enjoyable and engaging virtual experience. One aspect that received appreciation was the virtual environment’s ability to cater to various needs and interests. For instance, users entered the platforms with diverse group sizes and engaged in various types of conversations. The virtual space was constructed with these differences in mind, allowing users to choose the environment that best suited their needs and resulting in an optimal social experience: “It really helps [build social connection] since we can move to different rooms and each of them have different usages. For example, if we have few people, we can go to the classroom or conference room, while we have more people, we can go to the stadium.” (P53, desktop)

Regarding the nature of discussions, participants found it valuable to have a spacious and unrestricted area. This provided them with a personal and confidential environment for communicating with others, while also instilling a sense of safety and preventing privacy issues: “I did like how the world is very vast and wide open, allowing users to have private space if need be.” (P39, desktop); “I noticed no real threats to privacy, as individuals had to be friends with others in order to enter their rooms in the virtual world.” (P40, VR headset)

While some participants formed a feeling of “welcoming” and intimacy with others through private conversations, others preferred to engage in more public interactions. For example, P25 (desktop) derived pleasure from being stationed at the virtual space’s spawn point, where new participants would first appear when entering the application, and chatting with each of them: “The virtual world was key in facilitating social interactions, the way the space was set up it made it easy to talk with people. I was located in the spawn points so when people would appear I could talk with them, it was very nice to be the first point of contact when they entered and just have a brief chat.”

Social VR platforms have also developed dedicated areas for underrepresented communities to gather and connect with each other. These spaces were also intended for individuals outside of these communities to learn more about
them. One such example is the Crystal Ballroom exhibit. P63 visited this exhibit during one of the sessions. As P63 (desktop) described, “It had a little welcome structure that gave you information about it. I learned that this was built for someone named Keao, who is blind. In this informational message, they explain they wanted a ballroom because it was the first place they visited in [the virtual world] and they love to dance. They also explained some of the features like the chimes and talk about how they wanted a space that was inclusive for people to hang out in since there is a mixture of people with many interests in the blind community.”

In addition to the inclusive design that accommodated all kinds of needs, participants recognized the diverse offering of themes and room settings as key factors that influenced their virtual experience and social interactions. For example, P47 (desktop) indicated that the diverse designs and themes “helped build social connection” by making him feel a sense of presence and engagement within the virtual space: “the set environments may have helped in building social connections: seating, soccer fields, beaches. I found it enjoyable and oddly immersive.” On the other hand, P63 (desktop) thought that the different room settings were created with social interaction in mind: “I think the different room settings were a great feature to guide the social interactions to happen in a certain way.”

Others held this view as well and provided specific examples based on their close-up observations of how interactive objects encouraged user engagement and initiated interactions with both the environment and other users: “Users could interact with objects in the environment. Users picked up firecrackers, lit them up by getting close to the bonfire and played with them. This activity got many people engaged and interacting with each other.” (P11, desktop); “I think the buildings in this virtual world are very interesting, such as the circular painting gallery, the jungle wooden house, and the living area of the elephants, which are very diverse and interesting. The elephant will hit our avatar, and there are many interesting small objects to interact with.” (P19, desktop)

According to the participants, the diverse themes and interactive objects that were unique to each setting were greatly appreciated and were seen as an important factor in creating an immersive experience and promoting social interaction. In addition, they expressed a desire for even more interactive elements. This sentiment was expressed by P51 (desktop), who said: “I liked how I was able to interact with certain objects, chairs, boats, etc and wish there were a bit more interactive elements (but it was still nice nonetheless).”

As demonstrated in participants’ own account, having a wide selection of themes featuring unique interactive objects attracted individuals to fully engage and immerse themselves in virtual environments that suit their interests and preferences, thereby enhancing their overall experience. Furthermore, this diversity fostered the formation of distinct social interactions and even influenced the nature of interactions within the virtual space.

**Dynamic audio feedback supports effective communication**

Participants in this study believed that the use of audio feedback was an essential feature that improved their communication with others. One participant, P11, specifically appreciated the ambient noise present in each environment, which added to the realism of the virtual experience. P11 (desktop) stated, “The application gave importance to audio feedback. There was an ambient noise unique to each environment. Further, I could hear whispers of people talking if they were away from me and just like in real life I could go closer and become a part of the conversation.”

In support of his argument, P11 presented concrete examples to illustrate how the environment utilized distinct audio features to meet varying communication needs: “I found it extremely interesting and useful that the environment applied both spatial voice and flat voice depending on the requirements of the meeting. In conference rooms, flat voice was used which means everyone in the room could hear the speaker. On the other hand, if users moved into private areas or were outside the rooms spatial sound was used which promoted private conversations.” P11 found this approach to be both intriguing and beneficial, as it optimized the effectiveness of communication in different settings.

P63 echoed this view and further emphasized the positive impact of dynamic audio feedback on enhancing social connections in social VR. As P63 (desktop) noted, “[the virtual world] was helpful in that we could talk to the whole class or more privately to the people around us.” Moreover, P63 found that the spatial voice, which automatically adjusts the volume based on the user’s proximity to others, “makes it feel more personal”, creating a sense of closeness and connection.

**Being able to customize and control the avatar enhances user interaction**

The avatar, which is the representation of users in the virtual environment, was considered a critical element in fostering social connections in the virtual environment, setting it apart from other communication mediums. For instance, P39 (desktop) noted: “I think it helped me build social connections cause there was an added dimension of the avatar when compared to a Zoom call. In a Zoom call, you can only see a screen but in [the virtual world], you have the avatar to control which gives the interactions more depth.” According to P39, the avatar offered a unique dimension to interactions, enhancing the social engagement experience beyond what is possible on video.
conferencing platforms. Echoing P39’s opinion, other participants remarked on specific aspects of the avatar that promoted social interactions. One of these aspects is the ability to be customized based on user preferences, as noted by P63 (desktop): “Having avatars that are customizable to resemble you makes you feel more present.” P63 suggested that the personalized avatars heightened users’ sense of presence, leading to a more immersive experience. P11 (desktop) also appreciated the ability to modify the avatar’s appearance, stating that “everyone's avatars looked interesting and unique” after customization. P11 found this diverse range of visual representations enticing and suggested that the avatar’s customizability encouraged social bonding in the virtual environment.

According to participants, another crucial aspect of the avatar is its ability to mirror users’ movements and actions. P49 (VR headset) described how the avatar’s hand gestures and body motions were effective in indicating active listening and conducive to social connections: “[The avatar] was built for conversation, ... you could act out a series of hand gestures with a button click, and there were rendered hand gestures and body motions that showed that you were listening to others speak. It was very conducive for social connections.” P21 (VR headset) appreciated the avatar’s ability to resemble users’ real-life head and hand movements, making the interactions feel more natural and realistic: “It was quite interactive and I liked that our avatars would indicate who is talking. For those wearing the headsets, it was interesting to see the real-life head and hand movement.”

Furthermore, participants found that having control over their avatars enhanced their virtual experience and made it easier to interact with others. As P36 (desktop) put it: “The ability to do casual actions like dance made the experience a lot more informal and easier to connect with people.” Similarly, P41 (desktop) highlighted how the ability to control their avatar and perform real-world actions helped them build connections: “I could use my avatar to interact with other people's avatars using much of the same principles as the physical world. For example, I could run, jump, sit, shift gaze, dance, and interact with objects such as projectors, tables, soccer balls, and even drive a boat.”

In summary, the avatar’s customizability, ability to mirror users’ head and body movements, and to perform actions as in the real world elicited a strong sense of presence, immersed users in the virtual environment, and facilitated interactions and social connections among users.

**Communication modalities and social activities help build connections**

Guided by the principle of enhancing social interaction, social VR platforms have integrated multiple communication modalities to create a seamless and effective social experience. For example, P49 highlighted the value of face cams and microphones in building social connections as they enabled users to show expressions and observe the reactions of others. According to P49 (desktop), “utilizing face cams and microphones in addition to avatars in a virtual space mimics a real in-person experience”, making it possible for individuals to interact with each other in a more authentic and natural way.

Besides face cams, avatars played a crucial role in providing non-verbal cues in virtual spaces, such as head and body movements, and physical expressions. P14 specifically appreciated the use of head nodding by avatars, considering it to be “a very underrated non-verbal communication cue”. According to P14 (VR headset), the combination of verbal and non-verbal communication modalities in the virtual space made it “a lot easier to connect and communicate with people”. Additionally, P11 (desktop) noted that the tracking of hand movements “significantly improved communication”, while P29 (VR headset) concluded that synchronous head and hand movements of avatars created “a sense to talk in reality” that fostered a great feeling of communication.

In addition to verbal and non-verbal communication, the availability of various emojis also made the communication experience more enjoyable and interactive: “There were a variety of emojis such as hand raise, clap, blush, sad, happy, etc. to choose from to communicate.” (P11, desktop)

Alongside offering communication options that cater to users’ communication needs, social VR platforms have also facilitated numerous social events to promote interaction and engagement among users. P45 (desktop) expressed appreciation towards these events, stating “I liked aspects of it, like that there are live events and concerts, which makes it feel like a real place people can go to for socialization.” Likewise, P66 praised the feature of watching videos together. According to P66 (VR headset), this feature was “good for small group interactions” and “provides users with a shared sense of immersion” that enhanced community building. These social events and features helped create a sense of togetherness and community in the virtual experience.

**BEYOND CONNECTION: THE ADDED BENEFITS OF SOCIAL VR**

**Social VR offers a cozy and secure setting for disclosure**

While the survey question focused on the ways in which social VR platforms enhanced social interaction, some participants also discussed their effects on self-disclosure. For example, participant P64 (VR headset) noted that “the virtual world made it easy to talk to people in my class because we were all hidden behind avatars and online.” P64’s experience suggests that the use of avatars could potentially encourage greater self-disclosure in virtual
environments. Since self-disclosure typically necessitates a private setting, the platforms included designated areas for private conversations, as described in the first section. These features were highly valued by participants, who noted that they "took privacy into account" and helped foster personal connections. As P33 (desktop) described, "there were privacy zones where only people in the zone could hear each other talk. The doors to some rooms were also lockable." P19 (desktop) even suggested that such rooms "could be used for student consultations."

### Social activities bring relaxation and help overcome social anxiety

As presented in the first section, social VR platforms organized various events and activities to bring users together and connect with each other. Not only did these activities foster connections among users, but they also "bring relaxation." One example is the 3D painting activity described by P25 (VR headset). As they noted, "the experience was pretty good because we had a goal to work towards rather than just chatting on a virtual space ... working together to achieve something works much better in developing a sense of relaxation than cold conversation does." The excitement of the activity also added to the enjoyment of the experience. Another participant, P43, recounted an experience where virtual reality enabled him to engage in activities that they may not have felt comfortable doing in real life. As P43 (desktop) described, "at first I just stood in the Haptics room watching people doing Gangnam Style and I felt awkward. But then I realized I am not the one dancing and was just going to make my character do it, and somehow in real life making my avatar dance made me feel more at ease." This example demonstrated that the sense of anonymity and distance provided by the avatar in the virtual environment can help individuals overcome social anxiety and enjoy social experiences that they may not have in the real world. As P65 (desktop) noted, "virtual worlds were a good method of creating social connections, especially for those who have trouble doing so in the real world." These findings suggest that social VR platforms can provide users with a unique social experience, which may help improve their mental wellness.

### DISCUSSION

The findings of the study suggest that social VR platforms have the potential to enhance social interaction and improve the mental well-being of college students in a class setting. Among the design choices listed in the taxonomy by Handley et al. (2022), virtual space construction, avatar representation, and communication types and activities were identified as key contributing features to students' social experiences in social VR. In addition, audio feedback, which was not included in the taxonomy, was also recognized as a key facilitator of social interaction in the virtual space. Moreover, there is evidence to support the findings from Freeman and Acena (2021) and van Brackel et al. (2023) that using social VR may improve users' social skills. Students reported that social activities brought relaxation and helped overcome social anxiety, encouraging them to do things that they found hard to do in the real world (e.g., dancing with a crowd). Such experiences may facilitate individuals' social interactions in the physical world and enhance mental wellness. Additionally, the study found that social VR platforms provided a safe and comfortable environment for students to disclose personal information. This discovery suggests that social VR platforms are capable of facilitating both casual and formal disclosure, making them ideal platforms for the delivery of mental health services, such as individual and group counseling. Finally, this study underscores the importance of offering students the flexibility to choose their preferred device for accessing social VR platforms. The results revealed that a considerable proportion of students may still prefer desktop access despite the lower level of immersion. Nevertheless, the key features of social VR platforms remain effective in promoting social interaction and providing an engaging virtual experience. Interestingly, the unique affordances of VR headsets, such as head and body movement tracking, have also been shown to benefit desktop users, as it helps them pick up on nonverbal cues from their VR counterparts. Overall, the study suggests that social VR platforms have the potential to enhance social interaction and promote mental well-being among college students, regardless of the device used for access.

### SOCIAL VR ENHANCES SOCIAL INTERACTION

This study confirms the findings of previous research that virtual environments have a significant impact on building social connections. One notable aspect that received appreciation was the diverse offering of themes, rooms, and spaces in the virtual environment, which catered to different group sizes and interests, enabling users to engage in various conversations. Furthermore, interactive objects that complemented the themes enhanced the immersive experience, increasing user engagement and enjoyment. These results align with previous studies that highlighted the role of virtual spaces' design in improving user experience and engagement (Jonas et al., 2019; Maloney et al., 2021; McVeigh-Schultz et al., 2019). This study also reveals that social VR platforms have developed dedicated areas for underrepresented communities to connect and interact, creating inclusive spaces that foster a sense of belonging. This finding is consistent with Acena and Freeman's (2021) research, which highlighted that social VR offered a safe space for marginalized communities.

Sound is a crucial component in creating an immersive virtual environment. However, previous studies evaluating design choices in social VR (Handley et al., 2022; Jonas et al., 2019; McVeigh-Schultz et al., 2018; McVeigh-Schultz et al., 2019) may have overlooked its importance. In contrast, participants in this study frequently cited sound as a key facilitator of social interaction. They praised the ambient noise for making the environment feel
more realistic, which supports Bulu’s (2012) statement that sound, along with texture, light, motion, and other details, can bring realism to the virtual space and thus create a more immersive experience. Furthermore, this study highlights the value of using a combination of spatial and flat sound to accommodate different communication needs. The flat sound, which projects the voice at an equal volume within a restricted area, was helpful during lectures and presentations in classroom settings. While the spatial sound, which adjusts the volume based on user proximity, promoted personal interaction, fostering a more intimate experience and a sense of closeness.

Students found the avatar to be a critical element in fostering social interaction in the virtual environment, providing an added dimension that sets it apart from other communication mediums. Specifically, the avatar’s customizability, combined with the ability to mirror users’ head and body movements, was found effective in enhancing the sense of presence and fostering social interaction. These findings align with those of Han et al. (2022), who observed that personalized avatars, particularly those resembling users’ appearance, were preferred by students as they allowed for a distinct self-presentation, thereby improving their experience and group dynamic in social VR.

There was also evidence to suggest that communication modalities, along with meaningful social activities, can enhance the authenticity and naturalness of social interaction in social VR. Namely, face cameras and microphones facilitated the exchange of verbal cues and non-verbal expressions, which are important for social interaction (Handley et al., 2022; Jonas et al., 2019; Maloney et al., 2020b; McGivney et al., 2022). Face cameras, in particular, complemented avatars by conveying minute non-verbal cues that were not reflected on avatars. This finding supports the research of McGivney et al. (2022) that having video chat open while using VR created a shared experience, making students feel more connected to their classmates. Emojis were also found to make communication more enjoyable and interactive. Moreover, this study aligns with previous research that social events enhance community building and create a sense of togetherness (Maloney & Freeman, 2020; Zamanifard & Freeman, 2019). As noted by Maloney and Freeman (2020), “these findings point to social VR’s potential to afford a wide range of social connectivity and forms of interpersonal relationships”.

SOCIAL VR PROVIDES UNIQUE BENEFITS REGARDLESS OF THE DEVICE TYPE

The study found that despite having access to VR headsets, most students in the study still used desktops to engage with social VR platforms at least once. This preference for desktop access has been observed in other cases, including virtual conferences (Ahn et al., 2021). However, the experience of non-VR users in social VR is still not well understood as most existing research has primarily focused on the VR perspective (Maloney & Freeman, 2020; Maloney et al., 2020a; Maloney et al., 2021; Moustafa & Steed, 2018). Previous studies have compared the differences in user experience between VR and desktop in VR gaming applications and found that users reported a greater sense of presence in the headset environment, leading to a higher level of immersion and engagement. Nonetheless, this increased presence did not necessarily translate to a more satisfactory experience (Carroll et al., 2019; Berkman et al., 2020).

While this study did not provide an empirical quantitative comparison of the user experience of social VR through different devices, the results suggest a similar trend: the lower level of immersion does not seem to hinder desktop users' interaction with others in social VR. They report similar appreciation and identify the same features as beneficial for building social connections. However, this study still indicates some discrepancies in user perception of the features. One notable difference is that the audio feedback in the platform primarily came from desktop users. This could explain why previous studies on social VR did not recognize it as a key feature. A potential explanation is that VR users were already so embodied in their avatars and immersed in the environment that audio feedback, especially spatialized sound, blended into their experience seamlessly. In contrast, desktop users are less embodied and still receive sensory cues from the real-world surroundings, making them more likely to notice the different audio feedback and recognize its role in facilitating social interaction.

Despite these differences, the study confirms that the benefits of social VR are not limited to VR headset users, but also extend to those accessing the platform via desktops. In particular, head and body movement tracking, previously highlighted as a unique advantage of social VR experience, also received appreciation from desktop users as it allowed them to perceive nonverbal cues when communicating with their VR interactants. Although desktop access may not provide the same level of immersion as a VR headset, it still offers a satisfying social experience, as well as potential mental health benefits. Based on these findings, future studies should delve deeper into the experiences of users who access social VR platforms through other devices to develop a more comprehensive understanding of how the experience differs.

SOCIAL VR ENCOURAGES SELF-DISCLOSURE AND SUPPORTS MENTAL HEALTH CARE

The finding that the level of anonymity provided by avatars can facilitate communication among students is consistent with Maloney et al.’s (2018) research, which suggests that people are more likely to share personal information when being anonymous. Furthermore, users were more comfortable disclosing their emotions and life experiences than other identifying information such as age, gender, and location. Baccon et al. (2019) also reported
that VR platforms tend to elicit more frequent cognitive and emotional self-disclosure than other computer-mediated communication channels, and they attributed this to the richer set of communicative cues available in VR, which makes VR an effective platform in eliciting self-disclosure, suggesting that VR has the potential to be as effective as in-person communication in eliciting self-disclosure.

This study adds to the discussion by emphasizing the importance of having private areas for self-disclosure in social VR, a factor that has received little attention in existing research. According to students, the designated privacy zones with lockable doors and enclosed audio feedback provided a safe and realistic environment for them to discuss personal and private topics with their close network. This finding suggests the potential of social VR to serve as a platform for the delivery of professional mental health care services, such as individual and group counseling, which require an enclosed and safe space.

Virtual reality has been gaining attention as a potential tool for delivering therapy and counseling services, particularly in light of the COVID-19 pandemic, which has led to an increased need for remote mental health services. While previous studies have demonstrated the effectiveness of VR in treating psychological disorders (Freeman et al., 2017; Hoffman, 2004; Maples-Keller et al., 2017; Paul et al., 2022) and providing counseling services (Lin et al., 2021; Sarpourian et al., 2022; Wray & Emery, 2022), these studies were typically conducted on self-developed platforms rather than publicly available social VR applications.

Despite the lack of literature, social VR platforms have shown promise as a means of providing mental health support. According to Kelley (2021), 17.8% of social VR users have used these platforms to cope with COVID-19 anxiety and social anxiety. Our study also found that participation in certain social activities in social VR helped students overcome social anxiety and feel more relaxed. Overall, these findings suggest that social VR platforms can serve as a valuable supplementary tool for mental health care, as they offer a secure and comfortable environment for self-disclosure and can facilitate the delivery of professional mental health services. In particular, the avatars, designated private areas, and additional communication modalities remove barriers and address concerns around revealing personal insecurities, making them ideal for personal disclosure and formal consultations. Moreover, the accessibility of social VR makes them a convenient and cost-effective platform for delivering mental health services: providers who lack the resources to develop a standalone VR system can easily customize their virtual space to provide the best possible service, and clients can still benefit from the social interaction and immersive experience of social VR even without a VR headset. As social VR continues to evolve, more research is needed to better understand how the platforms can be leveraged to support mental health care.

LIMITATIONS
Although the study was conducted across large educational institutions in the United States, the sample may not be representative of the general college student population. This is because students were asked to opt in to participate in the study, which could have biased the sample towards those who were more engaged and enthusiastic, and away from those who were more concerned about privacy and anonymity. Additionally, it is possible that students who enrolled in VR-focused courses had a pre-existing interest in the topic, which could have influenced their willingness to explore different options. To address these limitations, future studies could consider surveying students in non VR-focused courses to obtain a more representative sample of university and college students in general.

CONCLUSION
The study investigated the effectiveness of social VR platforms in promoting social interaction among college students, identified key facilitators, and examined the platforms’ potential to serve as a platform for mental health care services. The evidence gathered through this study demonstrates that the virtual space, sound, and avatars immersed students in the virtual environment, communication modalities facilitated an effective exchange of information, and social events created a sense of togetherness. These features were integrated to promote social interaction, which has been shown to enhance perceived social support and connectedness, and improve the mental well-being. In addition to enhancing social interaction, social VR has the potential to support the delivery of mental health services. The study found that the anonymous nature, communicative cues, and designated private areas provided by social VR platforms create a safe and comfortable environment for students to disclose personal information, opening up opportunities for formal consultations. The accessibility of social VR also makes it an attractive platform for mental health professionals to reach students who are reluctant to seek traditional forms of therapy or lack access to mental health services.

ABSTRACT
Beyond the easy and equal access to massive online contents, will digital reading bring more social welfare values for disadvantaged groups? Take left-behind children (LBC) in rural China as example, whose mental health issue has widely aroused public concern. Lacking of sufficient parental supervision and educational resources leads to insufficient development of psychological resilience and makes them vulnerable to mental health problems. As psychological resilience is a critical protective factor for maintaining mental health, in this paper, we wonder whether digital reading could perform as an alternative way with easy accessibility and numerous resources to supplement LBC’s resilience development. We conducted a field questionnaire study on LBC (N=217) and investigated the predictive effect of digital reading on psychological resilience. After controlling sociodemographic variables and common resilience protective factors, hierarchical regression results demonstrated that digital reading predicted an additional 4.3% of the variation in resilience above the control variables, indicating digital reading a positive promoter of LBC’s psychological resilience. Moreover, by systematically exploring the fine-grained digital reading variables, we also found intrinsic motivation to read and recreational digital reading (e.g., reading comics and communicating online) to be the two most stronger predictors of psychological resilience.

KEYWORDS
Digital reading, left-behind children, psychological resilience

INTRODUCTION
The recent decades have witnessed the rapid progress of urbanization in Chinese society. Tens of thousands of people from rural areas have flooded into cities to join the labor force. To save the living cost in cities, most of them have to leave their children behind in the countryside. The social group of the so-called left-behind children (LBC for short) in rural areas has then been created, comprised of those under the age of 18 whose parents leave to work in cities and are taken care of by elderly relatives or even left unsupervised (Yan, 2022). According to the National Bureau of Statistics of China, the population of left-behind children in rural areas has reached more than 12 million by 2020 (http://www.stats.gov.cn/tjsj/ndsj/2021/indexch.htm). It is known that adolescence is a critical stage in the formation of one’s personality and values. Appropriate company and supervision from the family helps children grow up healthily. In comparison with other children, the lack of family companionship and mental health education in rural schools makes LBC more easily to suffer from a variety of psychological problems, such as anxiety, depression, etc. (Zhang et al., 2022), which negatively affects their growth. Thus, concerns for the healthy development of left-behind children in rural regions, particularly their mental health, has aroused wide attention in China.

Psychological resilience, as a personality or a coping process that enables individuals with continuous self-adjustment in a positive manner under adversity, is a critical protective factor to keep mental health (Connor & Davidson, 2003). Amid the adversity of low social support, resilience is a necessary asset for LBC’s growth (Fan & Fan, 2021). Resilience has played the role of a prominent mediator in the association between self-harm and suicidal ideation for Chinese LBC (Li et al., 2020). Unfortunately, well-established findings have shown that the resilience of LBC is significantly lower than that of non-left-behind children (NLBC), which means that LBC are more vulnerable when confronted with negative life events (Dong et al., 2019; Guang et al., 2017).

Therefore, to improve LBC’s mental health, it is of great significance to find the way to help develop enough resilience. Previous studies showed that psychological resilience of LBC positively correlated with mother’s education, intimacy with cohabitants, and the number of close friends. A higher level of mother’s education, more intimate with cohabitants, and more close friends are always related to stronger psychological resilience (Xiao et al., 2019). However, the dilemma comes on the one hand that most rural left-behind children are facing the situation of lack of parental supervision and family companionship (Xiao et al., 2019). On the other hand, the rural schools where left-behind children attend usually lack mature caring mechanisms and sufficient educational resources, making it difficult for rural left-behind children to make up for the lack of family care through campus life (Pan &
Ye, 2014). Obviously, it is necessary to explore other available channels to help develop their psychological resilience.

With the development of media technology and mobile devices, digital reading is now becoming increasingly prevalent and has brought tremendous changes in reading practices and behaviors (Clinton, 2019), speeding up and simplifying access to information (Lizunova et al., 2022). Reading on digital devices (e.g., smart phone, tablet, computer or e-reader) instead of printed paper, digital reading provides easy and equal access to massive knowledge and contents via the Internet for everyone (ChanLin et al., 2015; Kuhn et al., 2022). Recently, the number of young digital readers has increased dramatically as well (Mills, 2010). Statistics show that digital reading users in China reach 506 million by 2021, with 44.63 % aged 19-25 and 27.25 % under the age of 18 (http://m.cadpa.org.cn/3277/202206/41513.html). As a common daily activity, reading promotes children's physical and mental development. It can provide children abundant knowledge and information to develop their intelligence, broaden their horizons and enhance their cultural accomplishment (Arnesen et al., 2019). Moreover, reading has further been developed into psychological therapy. The popular bibliotherapy uses books or stories to help people understand personal problems and improve emotional healing, which inspires children to find unique solutions to control their lives through the identification of others (Bouchard et al., 2013). Children's literature has the potential to foster emotional growth and healing to some extent (Heath et al., 2005). Great stories change the way children think and feel, which in turn changes their behavior spontaneously (Heath et al., 2017). Quality picture books help children learn more about resilience theories or compare their own behaviors with the examples of resilience-based behaviors in the books (Tillott et al., 2022). Inspired by previous findings that traditional paper reading enhances children’s mental health development, we wonder whether digital reading may also contribute to it.

In this paper, we are aiming to shed light upon the relationship between digital reading and LBC psychological resilience by leveraging self-report questionnaires upon LBC in Lushan County, Henan Province. We systematically explored different fine-grained digital reading variables (e.g., reading frequency, reading motivation, digital reading types, etc.). Hierarchical regression model was exploited to calculate the incremental value of reading variables in the prediction of resilience after the effects of other well-known resilience-related factors (i.e. positive coping style (Wu et al., 2020), parental autonomy support (Wang et al., 2007), self-control (Wang et al., 2007), autonomous goal motives (Ryan et al., 1989), basic psychological needs satisfaction (Wang et al., 2007), parenting style (Arrindell et al., 1983; Perris et al., 1980), social support (Sarason et al., 1987), self-esteem (Rosenberg, 1965), and life satisfaction) and some sociodemographic variables (i.e., age, gender, etc.) were accounted for. Besides, we also carefully examined the significance of each fine-grained digital reading variables when LBC resilience was concerned. To the best of our knowledge, this is the first study investigating the predictive effect of digital reading on psychological resilience and illustrating the potential social welfare value of digital reading.

LITERATURE REVIEW

Common Protective Factors of Resilience

In the field of psychology, great efforts have been made to investigate the protective factors of resilience, which could be categorized as social and personal factors (Wallace et al., 2001).

Social factors

Family and social supports provide people positive resources to lift themselves up from difficult situations (Friborg et al., 2003; Wilks & Spivey, 2010). Autonomy-supportive family environment, where parents accept children as who they are and encourage them to be themselves, makes children more resilient because such environment protects vulnerable individuals from shame and depression caused by negative information about their identities (Legate et al., 2019). Meanwhile, parental involvement has been likewise proven to be a significant positive and significant predictor of resilience (Asanjarani et al., 2023). Especially for LBC, psychological resilience was proved to be associated with mother's education, intimacy with cohabitants, and the number of close friends. A higher level of mother's education, more intimate with cohabitants, and more close friends are always related to stronger psychological resilience (Xiao et al., 2019). In addition, the LBC who have less contradiction with their guardian or more concerns about migrating parents have better resilience (Guo et al., 2015).

Personal factors

Numerous studies have revealed that self-esteem, self-control, life satisfaction, positive coping style, autonomous goal motives, and basic psychological needs satisfaction functions as personal resilience-protective factors.
